Overdrawn Accounts

YOU see these cases time and time again . . . Men whose bank accounts are ample, and who would never think of drawing checks against an inadequate balance—yet they come to you with health accounts that have been overdrawn for years.

For years they have been eating unwisely, exercising too little or too spasmodically, working—and playing—too hard at the expense of sleep and mental relaxation. Then, when fatigue dulls brains that must be at their quickest, they have resorted to artificial stimulation of some kind—oftenest, caffeine. Caffeine is one of the simplest, easiest ways of drawing checks on one's reserve energy.

The reserve energy doesn't last forever. Then the statement comes in, with figures in red ink—and they call on you.

When caffeine beverages must be forbidden these cases—or their use greatly reduced—Postum can be helpful. This delicious drink, the favorite in over two and a half million American homes, satisfies *harmlessly* the natural desire for a hot drink at meal time. Its sole ingredients are whole wheat and bran, well roasted and slightly sweetened.

Instant Postum, made with hot (not boiled) milk, instead of the usual boiling water, is a particularly valuable drink for children, old people, and undernourished adults.

POSTUM COMPANY, INC., Dept. P-N. H. 1, Battle Creek, Michigan

*to send the physician who addresses us a special gift package containing a
age of Instant Postum, together with samples of other Post Health Products,
the-Nuts, Post Toasties, Post's Bran Chocolate and Post's Bran Flakes.*

KAHN PIPETTES

FOR USE IN THE KAHN PRECIPITATION TEST

NEW KAHN PIPETTES, A, B & C
F. S. CO. 13-677

HERETOFORE, technicians making Kahn Precipitation Tests were handicapped in that they had no pipettes to meet the particular needs of this test. For the delicate measuring of antigen dilutions they were obliged to use ordinary pipettes. In using ordinary pipettes in the past, the technician usually indicated, with a wax pencil, the graduations involved in his work.

The new Kahn Pipettes are specially made to measure conveniently and accurately the minute quantities of antigen mixture.

Accurate Measuring of Antigen Mixture of Great Importance

The amount of antigen mixture in the various dilutions is of vital importance and these new pipettes are a means of their accurate measurement. The three pipettes (one for each of the dilutions) have capacities and graduations as follows:

PIPETTE "A"
For first dilution
Capacity 1.5 ml. Smallest subdivision, 0.05 ml.
Each, \$.70

PIPETTE "B"
For second dilution
Capacity 0.2 ml. Smallest subdivision, 0.001 ml.
Each, \$.70

PIPETTE "C"
For third dilution
Capacity 0.25 ml. Smallest subdivision, 0.0125 ml.
Each, \$.70

These three new Kahn Pipettes, together with our No. 13-675 Pipette, 1 ml. subdivided in 0.01 ml., form a complete series for Kahn Precipitation work.

THE MICROSCOPE OF TOMORROW New Spencer No. 40H

With
A Circular Stage and a Real
Mechanical Stage
Fork-Type Substage
Combination Divisible Substage
Condenser and Dark-Field Illuminator

The mechanical stage moves in straight lines to and from the operator and also laterally by 18 m/m thereby providing sufficient range to completely cover an 18 m/m square glass cover.

The movements are smooth and responsive and conveniently operated by the two buttons at the side of the stage where both may be reached by one hand. Aside from stage it is identical with our No. 4411 microscope when fitted with fork-type sub-stage operated by rack and pinion.

New Catalog M-29 features it.

Your **CHILD** *has a right to this* **Astonishing** *HEALTH* **Discovery**

Vita Glass . . . a remarkable new window glass . . . brings indoors the ultra-violet rays, the vital health rays of the sun, and builds stronger, healthier bodies.

WINTER need not be a season of fear and anxiety over your children's health, for now a wonderful discovery brings them the great health element of outdoor life and provides them with nature's greatest weapon in fighting disease.

This remarkable invention is Vita Glass . . . a new form of window glass which has the ability to transmit the healthful ultra-violet rays in sunlight, the rays which scientists have proved are nature's most effective bactericide and nature's finest tonic.

They enrich the blood, increase vitality, and have a decided beneficial effect on the whole system. Rickets, that dreaded disease of childhood, is caused by a deficiency of direct sunlight; and the treatment now universally ordered is frequent exposure to these ultra-violet rays.

Some of the results obtained with Vita Glass are astonishing. In one school where a ten months' test was made it was found that pupils in the Vitaglated room gained an average of 6.11 pounds against 2.83 pounds in the other class. The gain in height was 1.86 inches against 1.22, while absences due to illness were reduced 40 per cent.

Hundreds of thoughtful people have been quick to recognize the wonderful health ad-

vantages of Vita Glass and many installations have already been made in sun rooms, nurseries and playrooms. Over 100 hospitals have installed it. Vita Glass is easily and quickly installed—simply have the old panes removed and replaced with Vita Glass.

Let us send you the complete story of Vita Glass, showing the results that have been obtained and containing full scientific information which you will find absorbingly interesting. Free for the asking. Simply sign the coupon below and forward. Vitaglass Corporation, 50 East 42d Street, New York.

(G. I.)

Cleanliness Institute

*Established to promote public welfare
by teaching the value of Cleanliness*

AN industry is great only in proportion to the service it renders.

Recognizing this, the Association of American Soap and Glycerine Producers, Inc., (whose members make 75% of the soap used in America) has established Cleanliness Institute for public service.

The Institute is, first of all, a fact-finding agency. Then it is an instrument for spreading

the knowledge thus obtained.

It will deal with cleanliness in its broadest scope — not only the practical questions of health, comfort and efficiency—but also the relation of cleanliness to self-respect, behavior, character, aesthetics, and the higher values of life.

It is already cooperating with schools, health organizations, etc., carrying on its work along the following lines:

DEPARTMENTS

RESEARCH AND SURVEY
LIBRARY
ADULT EDUCATION

ADVERTISING
SCHOOLS
INDUSTRY

INFORMATION SERVICE
SOCIAL SERVICE
HEALTH

PERSONNEL

The following professional workers make up the staff of the Institute:

ROSCOE C. EDLUND, *General Director*. Formerly an executive of community chest and welfare federations and in other fields of public and social service.

W. W. PETER, M.D., DR. P.H., *Health Consultant*. Internationally known health educator. Associate Secretary of the American Public Health Association.

SALLY LUCAS JEAN, *School Consultant*. Consultant to child health organizations and Fellow of the American Public Health Association.

JULIA B. TAPPAN, *Director, School Department*. Formerly director of health ed-

ucational programs, and collaborator with the United States Bureau of Education.

C. MARGARET MUNSON, *Associate Director, School Department*. Formerly research assistant in the Department of Biology and Public Health at Massachusetts Institute of Technology.

CLIFFORD GOLDSMITH, *Lecturer, School Department*. Well-known as "Professor Happy," under which name he has given many successful health talks in high schools.

MARIE K. PIDGEON, *Research Librarian*. Graduate of the New York State Library School. Seven years of library service with the U. S. Department of Agriculture.

Cleanliness Institute has prepared data of interest to educators, health and social service workers, and those in allied professions. It invites organizations and individuals to use its facilities. Inquiries will receive careful attention. Address CLEANLINESS INSTITUTE, 45 EAST 17th STREET, (on Union Square), NEW YORK.

Autoclaves in Convenient Sizes for all Laboratories

THIS efficient gas-heated sterilizer is the popular type for use in Bacteriological Laboratories. Four sizes are obtainable, all of which are compact and convenient.

The sterilizing chamber is made of polished copper and is fitted with a pressure gauge and a safety valve to prevent excessive steam pressures. Gaskets are not required to seal the door of the chamber; it seats on a ground surface.

A water gauge is a part of the equipment of the boiler which is conveniently located under the sterilizing chamber.

This convenient autoclave is No. 14-475 in the Fisher catalogue. If your laboratory does not have a copy of the catalogue, ask for one.

Size	A	B	C	D
Diameter, chamber, inches	17	21	23	26
Length, chamber, inches	20	24	28	28
Diameter of door, inches	10	12	14	16
Each	\$200.00	\$240.00	\$340.00	\$450.00

LIQUID PEPTONOIDS WITH CREOSOTE

COMBINES the active and known therapeutic qualities of creosote and guaiacol with the nutritive properties of Liquid Peptonoids and is accordingly a thoroughly dependable product of definite quantities and recognized qualities as shown by the formula:

Each tablespoonful represents		
ALCOHOL (By Volume)	12%
PURE BEECHWOOD CREOSOTE	2 min.
GUAIACOL	1 min.
PROTEINS (Peptones and Propeptones)	5.25%
LACTOSE AND DEXTROSE	11.3%
CANE SUGAR	2.5%
MINERAL CONSTITUENTS (Ash)	0.95%

It acts as a bronchial sedative and expectorant, exhibiting a peculiar ability to relieve *Bronchitis—acute or chronic*. It checks as well a persistent winter cough and without harsh or untoward effect. It is agreeable to the palate and acceptable to the stomach—with merit as an intestinal antiseptic. Supplied in 12 oz. bottles.

Samples on request

THE ARLINGTON CHEMICAL COMPANY
YONKERS, NEW YORK

"Nuthin' I Like!"

©1928 M. L. CO.

HUNGRILY and expectantly he had gone to dinner. "Nuthin'" he liked—just things which "were good for him". String beans—he wouldn't eat them. Time had come for discipline. When told that he was to have none of a favorite dessert, he gave in. Smiling thro' his tears after the first few mouthfuls, he said, "I didn't know it, but I was likin' string beans all the time"

PERHAPS in your own home there is a small child who is finicky about his food. But you insist upon his having plenty of milk, cereals, vegetables and the other foods he requires, for you know that the growth of his body and his health depend upon the "building" foods he eats.

But how about yourself? Have you dropped into the habit of ordering what you like without regard to the foods you need to build and repair your body and to keep it in the best possible condition of health?

Diet is literally a separate problem for each individual. The "overweight" is usually too fond of

starchy, sugary and fatty foods and disinclined to eat vegetables and fruits, while the "underweight" often neglects the fattening foods he needs. Appetite is not always a reliable guide to correct eating.

Take time to find out what constitutes a properly balanced day to day diet for a person of your age—how much meat, fish, cheese and milk you require, how many sweet foods, and most important of all—how many vegetables. Don't forget the string beans or the tomato, King of the Vitamins. Raw salads, fruit, butter, cream and nuts are important parts of the regular food supply when taken in correct amounts. And six to eight glasses of water daily, please—mainly between meals.

Through a well-balanced ration, you can keep in good condition every part of your body—muscles, bones, vital organs, nerves, eyes, teeth and even hair. It is interesting to discover what each particular food contributes to the body—to know just what to eat if you wish to reduce your weight, or increase your weight, or keep it normal.

Incorrect diet is responsible for a vast number of ailments and lack of strength and vigor. It is estimated that three calls out of ten in doctors' offices are caused by faulty diet—errors that may be easily corrected.

For more enjoyment in eating and for better health from eating, learn what to eat.

Because our daily food needs are little understood by most persons, the Metropolitan Life Insurance Company has prepared a booklet, "The Family Food Supply", which tells what to buy and how, and includes diet and marketing helps for the housewife.

The best food is not always the most expensive, and the most expensive is oftentimes far from the best. The least costly foods can often be prepared in such a way as to give more nourishment and more taste-satisfaction than those which are extravagant in price.

By means of this booklet, the modern housekeeper can easily find out which foods her family requires. She will learn which foods are needed by a man who does heavy physical labor, which are necessary for the office-worker, which for herself and which for the growing child.

"The Family Food Supply" tells how to buy economically and should be used in connection with the "Metropolitan Cook Book". A copy of either, or both, will be mailed, free, upon your request.

HALEY FISKE, President.

ANTIRHEUMATIC FEVER SERUM

Antistreptococcus Serum Cardioarthritidis Concentrated (S. C. A. Serum-Equine)* for the treatment of Chorea and acute Rheumatic Fever, is now being prepared in the Mulford Laboratories, according to the method of Dr. J. C. Small of the Philadelphia General Hospital.

S. C. A. SERUM-Equine, in 20 cc syringes, permits of a dosage of from 10 cc to 20 cc, injected intramuscularly.

In addition, Streptococcus Cardioarthritidis Soluble Antigen (S. C. A. SOLUBLE ANTIGEN) is offered for the treatment of subacute and chronic rheumatism and as a supplement to the serum treatment, by building up an active immunity.

In 5 cc vials, dilutions one and two.

S. C. A. SERUM and S. C. A. SOLUBLE ANTIGEN are produced under U.S. Government license, and arrangement with the Rheumatic Fever Committee of Philadelphia.

While supplying materials for the continuation of extensive corroborative clinical studies, S. C. A. Products are now available in so far as the limited supplies will permit.

**S. C. A. Serum BOVINE Unconcentrated will be supplied for patients sensitive to equine serum.*

Autoclaves in Convenient Sizes for all Laboratories

THIS efficient gas-heated sterilizer is the popular type for use in Bacteriological Laboratories. Four sizes are obtainable, all of which are compact and convenient.

The sterilizing chamber is made of polished copper and is fitted with a pressure gauge and a safety valve to prevent excessive steam pressures. Gaskets are not required to seal the door of the chamber; it seats on a ground surface.

A water gauge is a part of the equipment of the boiler which is conveniently located under the sterilizing chamber.

This convenient autoclave is No. 14-475 in the Fisher catalogue. If your laboratory does not have a copy of the catalogue, ask for one.

Size	A	B	C	D
Diameter, chamber, inches	17	21	23	26
Length, chamber, inches	20	24	28	28
Diameter of door, inches	10	12	14	16
Each	\$200.00	\$240.00	\$340.00	\$450.00

... POLLENS ...

From our California and Oklahoma pollen Gardens, and from temporary laboratories in various sections, we supply fresh dry pollens for every season and every section of the country.

Our pollens are guaranteed to be true to name and dependable. They are cleaned, dried, bottled and sealed air tight as soon as collected, thereby preserving their strength.

Average price \$1.75; wholesale, average price, \$1.50 per gram. Short (Common) and Giant Ragweeds 25c per gram.

Pollens should be ordered now for 1928 delivery.

References, prices list and samples sent on request.

An important message to you about the *EFFICIENCY* of *VITA GLASS*

VITA Glass—the remarkable window glass that admits the healthful ultra-violet rays of sunlight—is open to the most searching investigation.

The proof of its value is so conclusive that Vita Glass is now being installed in hundreds of America's leading homes, hospitals, schools, apartment houses and office buildings.

All claims made for Vita Glass are based on actual results . . . on scores of experiences here and in England, where in 1924 Vita Glass was discovered and developed.

The facts prove beyond all question that Vita Glass at all times transmits a sufficient volume of the vital ultra-violet rays for all health purposes.

After weathering, transmission power stays constant

All glasses, from exposure, lose some of their ability to transmit visible and invisible light. This phenomenon is called "solarization." This process diminishes some of the transmission ability of Vita Glass during the first few weeks, but after that its transmission power stays constant and is more than ample to supply a sufficient volume of ultra-violet rays for every health purpose. This has been proven conclusively by all experiences and tests with Vita Glass over a period of years.

Biological tests conducted under the auspices of the Council on Physical Therapy of the American Medical Association prove that, even in winter, Vita Glass admits a sufficient amount of ultra-violet rays to prevent development of rickets—that dreaded disease of childhood. Furthermore, the general health effects were such as to show a

material gain in weight under Vita Glass as compared to ordinary glass.

Statements based on visible . . . provable results

The facts about Vita Glass are not based on theory, but on actual results—visible, provable results—upon the health of actual people:

School children in Smethwick, England, who in a ten-months' test increased their height and weight and decreased by 40 per cent absences due to illness.

Fathers, mothers and children in their homes, who are enjoying the tonic, invigorating effect of Vita Glass just as much today as they did two years ago, when it was first installed.

Patients in hospitals, whose recovery has been hastened. Hundreds of grateful patients enjoy its beneficial effects today.

The facts are yours for the asking. We want you to have the complete story, including a record of many convincing biological tests. We also want to tell you about some of our important installations.

Fill in the coupon today. Vita Glass can be purchased through all glass dealers or direct from the Vitaglass Corporation, 50 East 42d Street, New York.

The Precision Still is here shown mounted on the convenient storage tank—chemically pure distilled water on hand at all times.

PRECISION

automatic

STILLS

The Fisher Catalogue illustrates and describes the complete line of Precision Stills, see page 303. Electrically heated stills for use with either 110 or 220-volt current and also steam-heated and gas-heated stills are shown.

Continuous Production of C. P. Water

Accessible Boiling Chamber

The still is easily accessible for inspection and cleaning. The condensing dome may be removed quickly. Simply disconnect a union.

Efficient Condenser

The shell-type condenser is completely surrounded by cooling water. It has a large cross-section and will not clog.

Long Life of Heating Unit

The heating unit has an exceptionally long life and, while designed to be immersed, it does not burn out if heated for a short time while not immersed.

Construction

The still is made of polished copper. All parts which come in contact with distilled water are heavily coated with pure block-tin. The packing between the walls of the boiling chamber is asbestos which prevents the loss of heat by radiation.

Henry Ford says:

"Despite the advance in our standard of cleanliness within the last twenty-five years, I am certain we have merely touched the possibilities which are offered for efficiency and profit. Because they are unnecessarily dirty, certain industries now are compelled to get along with low grade labor. Let them clean up and they will find that they can command the services of men who are twice as intelligent and twice as productive."

—from the Autobiography of Henry Ford

These FREE Posters will help make washrooms pay

The fullest use of washing facilities by your workers pays dividends in better health, fewer absences, increased pride and loyalty, better morale and increased production. Here are some effective posters

printed in attractive colors—friendly invitations to make good use of soap and water. They are sent without charge. Put them in your plant and let them work for you. Write for a set today.

These posters are prepared for you by Cleanliness Institute, an organization to promote public welfare, efficiency and health by developing and circulating information emphasizing

the practical importance of Cleanliness in every department of human life. No charge is made for this service. The posters will be sent immediately on application.

CLEANLINESS INSTITUTE - 45 EAST 17TH ST., NEW YORK CITY

THE above advertisement is one of a series which, in business papers, is carrying a cleanliness message to industrial executives. The hand washing posters, prepared for their use, are available also in limited number to health organizations.

Widening the Telephone Horizon

*An Advertisement of the
American Telephone and Telegraph Company*

IN THE memory of many now living, Alexander Graham Bell made the apparently rash prediction that the day would come when we could talk to other countries, even across wide expanses of water. That was shortly after the historic conversation between Boston and Cambridge, a distance of two miles.

Bell's vision was made a reality when in 1926 New York and London spoke together in two way conversation, and when in 1927 this service was opened to the public between any point in the U. S. A. and Great

Britain. Since then, Mexico has been brought into speaking distance; important cities of continental Europe have come within the voice horizon of the United States.

Even more important, the Bell System in the United States now embraces 18,500,000 telephones—a growth for the past year of more than 750,000.

We may now converse with each other from practically any point in this country to any other, and may talk beyond our borders and across the sea. That is measurable progress in widening America's telephone horizon.

FISHER SHAKING MACHINE

For the Kahn Test

The New Fisher Shaking Machine with six Kahn Test Tube Racks in place.

Direct Driven For Correct Oscillations

TO INSURE the correct shaking rate of 275 to 285 oscillations per minute, this machine is directly connected to the motor, thereby eliminating the use of a belt.

Operates at 277 oscillations per minute carrying six racks of tubes and 281 oscillations carrying one rack of tubes.

Adjustable Capacity

This machine is designed to take care of the needs of both large and small laboratories, as it operates equally well with any number of Kahn test tube racks from one to six.

Price (without racks) \$70.00

110 Volts A. C.

Kellogg's

aid in Community Health

THE health of a nation is dependent upon the health of its people. Every citizen should feel that keeping well is a duty he owes to his country.

Kellogg's ALL-BRAN will help you to help yourself to health. Bland foods, sedentary work, and little exercise all contribute to the problem of constipation. Under these conditions the intestinal tract becomes lazy and as a result a large percentage of the people in this country are constipated.

An easy and pleasant way to avoid this disease is to include Kellogg's ALL-BRAN in each

day's meals. It is delicious as a cereal, with milk or cream; it may be combined with other cereals; mixed with fruits or soup, or eaten baked into bread or muffins.

The Health Service Department of the Kellogg Company has prepared a pamphlet on constipation.

Doctor Sun

THE world's greatest physician is located 92,000,000 miles away. He is Dr. Sun. And the one great medicine that he sends is sunlight. On bright, sunny days his free dispensary is open to everybody, everywhere. But in northern latitudes, his treatments—generous applications of ultra-violet rays—are most successful during the summer months.

Sunlight is the finest tonic and health-builder in the world. It works its cures, mysteriously, through the skin. In sunshine there is a wonderful healing power—the ultra-violet rays. These rays are most effective from April to November and are particularly strong from June to the end of September.

Ultra-violet rays do not penetrate ordinary window glass, or clothing except the very lightest in color and weight. Nor do they penetrate, to any great extent, smoky and dust-laden atmosphere. For those who can put on bathing suits and enjoy the sunshine at a beach on ocean, lake, or river, the problem of getting sufficient ultra-violet radiation is solved. But others, too, may receive the benefits of the sun's rays by using ingenuity. At some time during the day the sunshine usually pours into some room in the home where one may lie without clothing in its unobstructed light. A canvas tent without a top, in the yard or on the roof or open porch, will serve.

Sun baths, taken regularly, increase the red corpuscles of the blood in great numbers. The supply of calcium, iron and phosphorus in the blood is augmented. Many physical disturbances partially due to sunlight starvation—notably rickets and anemia—can be relieved by daily sun baths. Certain skin diseases can be healed more rapidly when treated by the sun's rays. Sun baths are a valuable tonic for the organs of the body. The ultra-violet rays kill bacteria and germs.

Dr. Sun's best office hours are in the early morning and late afternoon. At mid-day his treatment is more likely to scorch than to heal. Even at the best hours, over-exposure does more harm than good. It is a mistake to try to get tanned too rapidly. Excessive exposure, especially on parts of the body not accustomed to direct rays of the sun, may cause not only painful burns but also serious skin trouble. Exposure should be gradually increased from day to day.

So essential is sunlight to the body that science sought and has found a way to manu-

EDWARD J. STEIGER

facture ultra-violet rays that may be used helpfully in the winter and on days at other times of the year when the sun's rays are weak. But great care should be exercised. Artificial sunlight treatments may be extremely harmful if given by anyone not familiar with their power.

In praising the value of natural sunlight, one eminent physician says, "When we have added together all the healing virtues of the Finsen light and Radium and the Roentgen Rays, and all the uses of heat rays and electrical waves in the care of atrophied or unused muscles—when every particular form of radiation has been tried and exploited to the uttermost—the value of natural sunlight upon us, whether as therapeutic in certain forms of disease, or as hygienic and prophylactic, outweighs all these other things as the Atlantic outweighs the contents of the Olympic swimming pool."

Plan, definitely, to store up health. Get your share of the ultra-violet rays in summer, while they are at their best. A booklet, "Sunlight, the Health-Giver," tells of many benefits to be derived from the sun's rays. It will be mailed free upon request to the Booklet Department, Metropolitan Life Insurance Company, One Madison Avenue, New York City. Send for it.

Haley Fiske, President.

FISHER VIEWING APPARATUS FOR KAHN TEST

IDEAL ILLUMINATION

Four tubes are illuminated from the correct angle and with the correct light to view the precipitate comparatively.

EASY READING

Conveniently located on the front is a key, which actuates the support at the top of the test tubes. By operating this key the liquid in the tubes is given a slight motion without losing the illumination. This motion makes the precipitate distinguishable and thereby facilitates results.

The TEMPERATURE FACTOR IN THE WASSERMANN

ACCURATE automatic control of temperature in Wassermann baths depends on (1) close, positive regulation, and (2) good heat distribution. Good distribution results from correct design and construction of the bath. Good regulation requires a thermo-regulator sensitive to a fraction of a degree but at the same time strong enough to give a positive make and break at the contacts. It must also be easily adjusted to maintain either incubating or inactivating temperatures. These requirements are best met by the Cenco Dekhotinsky Bimetallic regulator shown above with which all Cenco Wassermann baths are equipped and which is one of the many reasons for the reliability of *No. 11336B Cenco Wassermann Bath*, with two racks for 96 tubes, thermometer, pilot lamp and electrical connectors at \$65.00

Another Headache

© 1928 M. L. I. CO.

"CLANG! Clang! Clang!" rang the bell in the old town-hall and at once the whole countryside was alert. The bell meant danger—usually FIRE!

"Bang! Bang! Bang!" goes the pain in your head—and it, also, is a warning of danger, perhaps grave danger, somewhere in your body.

Can you imagine any villager being stupid enough to cut the bell-rope because the clanging of the bell annoyed him—thus silencing the alarm while the fire raged? When you take a pill, or powder, or wafer to stop a headache, you may deaden the nerves which are carrying an important message of danger to your brain—but the "fire" goes on.

Headaches are usually symptoms of unhealthy conditions, perhaps in some totally unsuspected part of the body. There is almost no physical ailment which does not at some stage manifest itself in headache. Disordered kidneys or liver and intestinal difficulties, as well as nervous strain, infectious and contagious diseases often cause headache.

Fortunately the causes of the vast majority of headaches—indigestion, eye-strain, sinus and teeth infections and wrong posture—can be located promptly. But some of the obscure causes of headache can be found only by patient, skilful search. The trouble may come from a cause so remote from the head as a bone out of

place in the foot or a toxic condition from a diseased gall-bladder.

It is risky to attempt to diagnose your own headache. You may guess wrong and waste precious time prescribing for an imagined ailment while the real trouble grows steadily worse. To still the voice of pain without finding its source is like cutting the bell-rope and ignoring the fire.

Beware of headache remedies composed of habit-forming drugs which may injure the digestion, destroy red corpuscles of the blood, undermine the nervous system, depress or over-excite the heart action, and at best may give only temporary relief.

Give your doctor a chance to find the cause. While he is searching for the cause let him prescribe something to relieve the pain, if you must have relief.

A booklet giving helpful information about headache may be obtained free on request to Booklet Department, Metropolitan Life Insurance Company, 1 Madison Avenue, New York City. Ask for Booklet 7 A 8

An important recent development in infant feeding

The colloidal action of Knox Sparkling Gelatine is particularly desirable in the summer diet

THE colloid-chemical power of gelatine has been proved by Drs. Alexander, Bogue, Downey and other authorities. Gelatinized milk is being used by many physicians and in many institutions. It is more easily digested and absorbed. It increases the available nourishment of the milk mixture. Because it prevents the formation of large curds, it helps overcome regurgitation and vomiting. It is useful in the diet of infants with curdy stools, diarrhea, constipation, colic or excessive gas formation.

In addition to its proved value in infant feeding, Knox Sparkling Gelatine is an important adjuvant in the diabetic diet, where it increases protein content and satisfies the craving of the patient for bulk in his food. In liquid and soft diets, Knox Sparkling Gelatine adds variety to the menu with dozens of dainty appetizing dishes.

For 40 years Knox Sparkling Gelatine has been our one standard product. From raw material to finished package, every process in its manufacture is subject to constant chemical and scientific control. Knox Sparkling

CAUTION!

All gelatines are not alike. Many have added acid, flavoring and coloring matter. In the form of ready prepared desserts, they contain as high as 85 per cent carbohydrates.

Knox Sparkling Gelatine is a protein in its purest form, particularly suitable where carbohydrates and acids must be avoided. It contains more than 80 per cent pure protein (4 calories per gram) and has the same neutrality as milk.

Specify Knox when you prescribe gelatine and you will protect the patient from brands unsuitable for his dietary purposes.

Gelatine is all pure gelatine, unbleached, unflavored, free from sugar.

Valuable dietetic information available

Noted dieticians have prepared the following booklets, setting forth the value of Knox Sparkling Gelatine in medical practice, and offering many appetizing recipes for its use in the various prescribed diets. Data on interesting scientific tests is also available. Simply check the coupon below and mail it to us.

KNOX GELATINE LABORATORIES
Johnstown, N. Y.

The supremacy of the Therapeutic Carbon Arc is due to its versatility and efficacy

NO SOURCE of light is so versatile as the Therapeutic Carbon Arc. From a single lamp, several different kinds of therapeutic light can be produced by choosing from the several Eveready National Therapeutic Carbons.

You may produce light that contains substantially all the rays present in normal June sunshine, using Eveready National Sunshine Carbons. According to the U. S. Bureau of Standards, "Of all the artificial illuminants tested, it" (the sunshine carbon arc) "is the nearest approach to sunlight."

From other Eveready National Therapeutic Carbons you may obtain unusual intensities in various parts of the spectrum; ultra-violet, infra-red, and visible light of various wave lengths may be had in a number of combinations to meet the physician's requirements.

This versatility of the Therapeutic Carbon Arc means less

equipment for the physician or hospital to buy and operate.

It also means heightened efficiency. Exactly the light needed by each individual case can be had at will. Changing carbons is easy and takes little time. The carbons are polished and clean to handle. The full intensity of light is secured immediately on closing a switch. No excessive starting current is required. The efficiency of the arc is high; you get the maximum useful intensity at relatively low power cost.

A booklet has been prepared referring to authoritative works on typical medical uses of the Carbon Arc. This, as well as other literature describing the quality and other characteristics of Eveready National Therapeutic Carbons, will be sent to physicians and hospitals upon request.

Eveready National Therapeutic Carbons are sold by arc lamp makers and physicians' supply houses.

FISHER SHAKING MACHINE

For the Kahn Test

*The New Fisher Shaking Machine with
six Kahn Test Tube Racks in place.*

Direct Driven For Correct Oscillations

TO INSURE the correct shaking rate of 275 to 285 oscillations per minute, this machine is directly connected to the motor, thereby eliminating the use of a belt.

Operates at 277 oscillations per minute when carrying six test tube racks and at 281 oscillations when carrying one rack.

Adjustable Capacity

This machine is designed to take care of the needs of both large and small laboratories, as it operates equally well with any number of Kahn test tube racks from one to six.

Price, For 110 Volts A. C. (without racks) \$70.00

Also available for other currents

PRECISION AUTOMATIC WATER STILLS for Gas, Steam or Electricity.

These stills embody the most advanced ideas in still construction to avoid the difficulties inherent to other stills.

The water is automatically controlled, irrespective of the changes of pressure, as long as the water is running.

As there are no pipes in the condenser and the entire top of the still is removable, the crust can be more easily removed than in any other still, the entire interior being exposed and not a small hand opening only.

Electric units will not burn out immediately should the still run dry.

Overflow is taken from the cold, and not from the hot water, thus conserving heat.

These stills are made to stand on a table or to hang on the wall, or, if desired, may be superimposed on a block tin lined storage tank forming a very concentrated and desirable installation.

Circulars, prices and full information on application.

When ordering, please state voltage.

Father of PASTEURIZED MILK in New York says: "I WISH YOU SUCCESS"

"I WANT to express to you my great satisfaction that the importance of a pure milk supply is being recognized. Such an economic enterprise, added to individual philanthropic efforts, will help to spread ever farther the knowledge of the importance of pasteurization. I wish you much success in your work."

Mr.
Nathan
Straus
writes to
J. G. Cherry
Company
Expressing
Satisfaction

Knowing of some of the work that has been done by the J. G. Cherry Company in furthering the cause of hygienic milk, Mr. Nathan Straus wrote to us from his New York address, on March First. The above is an excerpt from the letter.

On the occasion of his birthday Mr. Straus sent us the above picture of himself and Mrs. Straus, posed beside a giant birthday cake on which was mounted a single candle.

Among the 500 letters of congratulations received by the noted philanthropist on his birthday were included those from President Coolidge and other leaders of nations of the world. The letters were bound into a volume and were considered by Mr. Straus as the best of the many gifts he had received upon the occasion of his reaching the mark of fourscore years. The benefactor who founded the pasteurized

milk law of New York state and milk stations in this and other lands and who, although once one of the wealthiest men of the world, spent the greater part of his fortune for the benefit of mankind, declared today that his charities are "selfish" in the sense that they do his soul good.

A postcard saying "Send Me the Two Books" and addressed to the J. G. Cherry Company, Cedar Rapids, Iowa will bring you two beautiful books. One gives a complete description of the methods of Cherry "7-Point" Automatic Pasteurization and the other is a picture trip through a number of famous milk plants.

Beware of Spiders

BACK of a partition where passers-by cannot see him, the loan shark spins his web—and waits. In his show-windows he displays generous-sounding proposals. He says, "We

will trust you when nobody else will—if you have a job."

Sometimes he boldly tells his story on posters and handbills—"Money for salaried men. No mortgages—no indorsement—no collateral—no questions asked. We let you have money at the time you apply for it." He pledges strict secrecy and low rates of interest. He describes himself as "the wage-earner's only friend in time of need"—spider-webs to catch the unwary.

The loan shark knows that the world is full of unfortunate men and women who will promise to pay almost any price in the future for a little cash in hand now.

Driven by extravagance or unexpected misfortune, the needy one, when caught, pays a truly terrible price.

The loan shark knows that many of his victims will be unable to pay on the appointed date. He, therefore, extends the time but increases the amount of the loan. Month by month it grows till it crushes. The loan shark's favorite lash on the unhappy victim is "Pay—pay more—or I will expose you. Pay or I will make you lose your job." Sadly enough, sometimes his threat is carried out and the job is lost.

Imagine a frightened employee paying \$2.00 a week "interest" on a \$10.00 loan for three years—156 weeks—and still "owing" the original \$10.00 although he had paid \$312.00. The man who paid this lived in the capital of a great State.

A man who made \$60 a month borrowed \$75 from a loan shark. For a period of three years, he paid each month \$21.85 interest—more than one-third of his wages—without reducing the principal debt.

The man past middle age who has never saved a cent can hope perhaps for but little more than continuing health and steady employment, but younger men and women can and should plan complete financial independence for themselves in their later years of life.

© 1918 M. L. L. CO.

If you must borrow, make sure the lender is licensed and supervised by the State.

A booklet prepared by the Metropolitan will be of assistance in showing how to avoid the loan shark's web. It will be sent free and without obligation on your part. Address Booklet Department, Metropolitan Life Insurance Company, Number One Madison Avenue, New York City and ask for Booklet No. 9 A 8

Haley Fiske, President.

Many millions of dollars are loaned annually by loan sharks. These millions in loans cost borrowers as much more in interest, together with untold mental distress.

Prosecution, though helpful, is not a permanent remedy for the loan shark evil. People still need money and will make any promise for the future in return for present relief. Legitimate remedial and business institutions are therefore necessary. Most States permit the chartering of limited-dividend, semi-philanthropic remedial loan societies.

The Uniform Small Loan Law drafted by the Russell Sage Foundation is in use in twenty-three States and has done much to better commercial money lending conditions in those States.

This Foundation has also assisted in the development of credit unions which are mutual loan and thrift associations. The credit union collects the savings of its membership and relays these savings to finance the individual needs of the same group.

The Department of Remedial Loans offers its assistance in organizing credit unions and remedial loan associations or in advising loan shark victims. Address, Russell Sage Foundation, 130 East 22nd Street, New York, N. Y.

FISHER VIEWING APPARATUS

For Kahn Test

IDEAL ILLUMINATION FOR THE PURPOSE

Four Tubes are placed in the rack and viewed under the conditions of illumination which most clearly show the floccular suspension in the tubes.

EASY READING

Conveniently located on the front, is a key which actuates the support at the top of the Test Tubes. By operating this key the liquid in the Tubes is given a slight motion without losing the illumination. This motion makes the flocculation more distinguishable and thereby facilitates the reading of the tubes.

Each \$25.00

Where the Bell System's profit goes

*An Advertisement of the
American Telephone and Telegraph Company*

THERE is in effect but one profit paid by the Bell Telephone System. This profit is not large, for it is the policy of the Bell System to furnish a constantly improving telephone service at the least cost to the public.

The treasury of the American Telephone and Telegraph Company receives dividends from the stock of the operating companies. It receives a payment from the operating companies for research, engineering and staff work. It receives dividends from the Western Electric Company—makers of supplies for the Bell System—and income from long distance operations.

Only one profit is taken from this money in the American Telephone and Telegraph Company's treasury. That is the regular dividend to its stockholders—now more than 420,000 in number—which it has never missed paying since its incorporation in 1885.

Money beyond regular dividend requirements and a surplus for financial stability is used to give more and better telephone service to the public. This is fundamental in the policy of the company.

The Bell System accepts its responsibility to provide a nation-wide telephone service as a public trust.

CHERRY-BURRELL PASTEURIZATION EQUIPMENT

*meets
every sanitary requirement*

THE household milk and cream in your community must be properly safeguarded as a public health measure. Proper pasteurization of all milk supplies is the surest method of insuring that all pathogenic bacteria are destroyed.

Two methods of postive pasteurization are available in our line. First, the batch or holding method. Second, the continuous or long-flow method. Both methods insure that every drop of milk will be perfectly pasteurized.

Cherry-Burrell Junior Pasteurizers meet the needs of the small milk dealer. Cherry Twin Coil Pasteurizers, Burrell Spray Pasteurizers and Burrell-Simplex Tubular Pasteurizer Systems meet the requirements of the medium and large volume milk dealers.

Your request for descriptive literature on pasteurization equipment will put you under no obligation.

CHERRY-BURRELL CORPORATION

Sales Offices: CHICAGO, DETROIT, CLEVELAND, CINCINNATI, COLUMBUS, INDIANAPOLIS, NEW YORK, BOSTON, SYRACUSE, PITTSBURG, PHILADELPHIA, BALTIMORE, CEDAR RAPIDS, ST. PAUL, LITTLE FALLS, N. Y., BROCKVILLE, CANADA.

Plan to visit the A.P.H.A. Convention in Chicago at the Stevens Hotel, Oct. 15-20.

If you are interested in looking over models of pasteurizing equipment, flush valves, etc., come to Booth 89.

A postcard saying "Send Me the Two Books" and addressed to the J. G. Cherry Company, (division of Cherry-Burrell Corporation) Cedar Rapids, Iowa, will bring you two beautiful books. One gives a complete description of the methods of Cherry "7-Point" Automatic Pasteurization and the other is a picture trip through a number of famous milk plants.

HEALTH AND WEALTH

A survey of the economics of world health

By LOUIS I. DUBLIN, Ph.D.

*Statistician, Metropolitan Life Insurance Company;
Secretary, Committee on Administrative Practice;
and Treasurer, American Public Health Association.*

DR. M. P. RAVENEL, Chairman of the Editorial Committee of the Journal, says of this book:

"Dr. Dublin has given us a book with which every health officer, health worker and statesman should be familiar, and which will interest all who are concerned in the welfare of humanity and the future of the race."

DR. HAVEN EMERSON, a member of the Executive Board, and Vice-Chairman of the Committee on Administrative Practice of the Association, says:

"This delightful book with its fifteen cameos of life-accounting, may well become a usual library volume, the text selected for a winter of club discussions, for a teachers' course in applied sociology, for public-health and civics classes."

**Convenient —
economical —
effective**
**Eveready National
Therapeutic Carbons**

EQUIPPED with any good arc lamp and a supply of the different types of Eveready National Therapeutic Carbons, the physician and hospital have an unusually versatile source of light.

Any desired therapeutic light may be secured. Sunlight may be practically duplicated. Special intensities in various parts of the spectrum may be secured, from the infra-red to the ultra-violet.

This versatility is secured from any one arc lamp, by the simple operation of changing carbons. No auxiliary apparatus is needed.

Where time is a factor, and it usually is in a busy practice and in a large hospital, the fact that the carbon arc functions at full efficiency immediately is of considerable value. There is no waiting while warming up. No excessive starting current. Cost of operation is low when wattage and carbon costs are compared with the useful intensities obtained.

A booklet has been prepared referring to authoritative works on typical medical uses of the carbon arc. This, as well as other literature describing the quality and other characteristics of Eveready National Therapeutic Carbons, will be sent to physicians and hospitals upon request.

Eveready National Therapeutic Carbons are sold by arc lamp makers and physicians' supply houses.

"He's a Great Boss!"

"He's been planning for you and the children as well as for me. He wants you to be protected in case anything happens to me. He's a great boss!"

WHEN you hear a man refer to his employer as "the boss," or "the chief," study the expression of the speaker's face. If the corners of his mouth turn up a bit and a happier expression comes into his eyes, you may be sure that his boss is kind and considerate. In some businesses it is the boss's privilege and personal pleasure to know by sight, and usually by name or nickname, everyone who works for him. And some of the great bosses in America, although they do not have the satisfaction of personal acquaintance, have earned the trust and affection of thousands of workers who have never seen them.

Perhaps there are still some employers who study ways and means to squeeze pay-rolls to the limit and who consider individuals on the pay-rolls merely as money-making units. But they will be replaced, sooner or later, by bosses who have a better understanding of changing industrial conditions.

Men cannot work collectively without

The efforts of employers to provide protection for the families of their employees are bringing a new spirit of good will into industrial relations. Ten thousand employers of labor in the United States and Canada have set up programs whereby their employees may secure insurance under most favorable terms. The necessity of medical examination is eliminated; family history becomes immaterial; so also the occupation of the individual; and cost to employees in each group is equalized.

© 1928 M. L. I. Co.

affairs, are glad to plan with them for the comfort and safety of their homes.

Cooperation of leaders and workers stretches the buying power of their joint dollars. In many cases it enables employees of an organization to

get life insurance protection at much less than it would cost to buy the same protection individually. Employees who have learned that the boss, buying for their entire group, can get better rates are glad to let him do their buying.

In this way, hundreds of thousands of families have already secured protection against possible financial disaster—at low cost. There will be more next year and more the year after.

Not only that, but when these Group Insurance programs are set up, employees are able to get their insurance at prices much below those available to individuals in the open market.

Employers and employees interested in Group protection plans are invited to send for free information on Group contracts to Metropolitan Life Insurance Company, Dept. 10A, 8, No. 1 Madison Avenue, New York City.

The Happy Day

"You surely deserve release from work and care. We owe our success to you and other men who always gave us the best they had. Pay days will be provided for you, as long as you live, out of the Cooperative Retirement Fund which you helped to build. You have earned the right to take it easy Good luck!"

© 1926 M. L. C.

AFTER the man who has won the right to retire in ease and comfort has been congratulated, the wise president and board of directors who thus show their appreciation of faithful service also deserve congratulations. Such appreciation inspires new courage in all hearts. The interests of capital and labor are inseparably linked. Through cooperative efforts their most difficult problems are being solved.

Many of the biggest employers of labor have learned that officers as well as men in the ranks do better work if they know that years of loyal service will be amply rewarded.

Stockholders expect dividends. Employees expect good wages. In wise management there is a fair and just division of

earnings which must be preserved in a delicate balance. Not all of the yearly earnings may safely be paid out in dividends and pay checks.

Long-headed business men make plans that permit the honorable retirement of veterans and the filling of their places by younger men.

Big business recognizes that it is good business to establish the independence of faithful workers in their later years. By planning together for their mutual advantage, employers and employees can build a sound Retirement Plan based on earnings and savings that will provide a regular, definite income for life.

No man of spirit wants charity but he does want an opportunity to become independent.

Business has welcomed the development of modern pension plans which have made possible retirement with a fixed income. While, in the past, many privately owned businesses have provided quietly for the needs of retired employees, scientific pension systems are a comparatively new development.

Some of the earlier plans, dictated more by good intentions than by sound financing, are so hopelessly involved that they will

have to be revised or completely abandoned. The Metropolitan Life Insurance Company has made a comprehensive study of more than 350 different pension plans in operation today. To employees and employers interested in a sound solution of pension problems, the Metropolitan will be glad to mail without charge, Booklet 12-A-8, "Sound Retirement Plans and What They Should Provide".

FISHER APPARATUS

FOR THE

KAHN TEST

FISHER SHAKING MACHINE
WITH SIX KAHN TEST TUBE RACKS IN PLACE

SHAKING MACHINE

To insure the correct shaking rate this machine is *directly* connected to the motor.

It is designed to take care of the needs of both large and small laboratories and

works equally well with one or six racks.

Price, for 110 volts, A.C. (without racks), \$70.00.

Also available for other currents.

VIEWING APPARATUS

Four tubes are placed in the rack and viewed under ideal conditions. Conveniently located on the front, is a key which transmits motion to the tubes. The precipitate in the tubes is thereby more easily distinguishable.

Each, \$25.00.

6 Advantages of the New FFSA

The more refined requirements of lens system formulae are satisfied by standardized objective mountings with threadless cells.

The fixed tube length makes for the best performance of objectives.

The Abbe Condenser has provision for the use of a dark-field lens element.

The patented fine adjustment assures long service through small number of parts and use of Butress thread, to absorb the lost motion, with twelve teeth in driving contact.

The Substage actuated by rack and pinion provides for long range movement.

The Simplified Mechanical Stage with rack and pinion movements at right angles has a range in one direction of three inches, in the other one inch and accommodates 3 x 2 inch slides. Stage racks completely off the microscope.

A RATIONAL ATTITUDE TOWARD CANDY EATING

Modern nutrition studies demand a thorough over-hauling of the old-fashioned idea that the eating of candy is a mere indulgence.

This is not an academic question, because the whole population eats candy more or less. From the public health standpoint, therefore, it would be a distinct advantage if people were guided in their candy-eating by sound nutritional principles as to its place in the diet.

For from the standpoint of Nutrition, candy is a food. From the standpoint of the Nutrition expert, the problem is to get people to eat it sensibly, and reckon it as part of the diet.

We, the National Confectioners' Association, are putting before the public, necessarily in popularized form, the modern findings on candy as a food. Suggestions from public health workers will be greatly appreciated. On the other hand, we will be only too glad to technically elaborate our general position, as stated in our advertising, to anyone interested in public health work. This division of our activities is under technical direction, which will be glad to furnish the necessary references to anyone who cares to consult the sources.

Has Prohibition Improved the Public Health?*

LOUIS I. DUBLIN, PH.D., FELLOW A. P. H. A.

I KNOW of no subject which in recent years has lent itself to more acrimonious and futile debate than the effect which the prohibition legislation has had on public welfare. On the one hand, there are those who trace virtually every favorable condition now prevailing in our country, including our unprecedented prosperity, to this enactment. On the other, writers and speakers equally sincere, utterly condemn the amendment and the enabling legislation because of its alleged corrupting and withering influence on the nation. They insist that we are becoming a nation of liars and of petty lawbreakers; that the flood of bad liquor is undermining the morals and health of our youth; and that these evils will grow with the passage of time unless we face about and change materially the letter and spirit of the enforcement law.

It is not my wish to add anything of a controversial character to this debate. I shall try rather to present a few new facts which are now available after a rather painstaking study which bear on the state of the public health during the recent years. I shall attempt to relate these facts to the prohibition situation, but this will not be an easy task. The time that has elapsed is short, the records are often defective, and the results confusing. Nevertheless, if we can keep our discussion free of bias, we may be able to throw light on the relationship between the new legislation and the public welfare.

DEATH RATE AS INDEX OF PUBLIC HEALTH

The best available index of the public health in the United States is the death rate. Reliable figures on the amount of sickness are almost altogether lacking. Two sets of mortality data are available. The first

* Read at the Forum Session of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

covers the general population residing in a large area of the country, known as the U. S. Death Registration Area as constituted in 1900. These are the 6 New England States, New York, New Jersey, Michigan and Indiana. Together, these 10 states contain 26.1 per cent of the total population of the country. Records of mortality have been kept with great accuracy in this area for the entire period since 1900. These states, moreover, are fairly representative of the country as a whole. While their people live chiefly in urban industrial areas, they have also a fair proportion of rural residents, namely, 25.0 per cent. The second group is composed of millions of men, women and children, who are insured in the Metropolitan Life Insurance Company and whose mortality experience it has been possible to follow very closely since 1911. They live in the cities and towns of the United States and Canada almost entirely. But, fortunately, they form so large a proportion of the communities in which they live that the very accurate figures we have on their life and health will do much to supplement the information that is available from the more limited public sources.

To observe the effect of the prohibition amendment, it is necessary to divide the period covered by the data 1900 to 1926 into two parts, namely, that prior to the adoption of the amendment and the period subsequent thereto. The year 1920 saw the establishment of national prohibition. That year would, therefore, seem to be the dividing line. Practically, it would be better to consider the earlier period as running from 1900 to 1917 inclusive, because the last three years, 1918, 1919 and 1920 were severely disturbed by the prevalence of the influenza pandemic, which distorted the mortality picture and gave an utterly false twist to the trend of mortality during the previous two decades. We shall, therefore, contrast the trends of population mortality in the two periods, that from 1900 to 1917, inclusive, with that from 1921 to 1926, inclusive.

The upper part of Chart I shows what has happened to the death rate in the general population of the original registration states. There was an improvement in mortality in the first 18 years, as is clearly indicated by the sharp downward inclination of the trend line. This is the heavy straight line running diagonally across the chart from 16 per 1,000 on the left in 1900 to a point a little over 14 per 1,000 on the right in 1917. It is the straight line which best shows the tendency of the death rate during the period when the actual death rates varied widely from year to year as is shown by the lighter jagged line. The average death rate in this pre-prohibition era was 15.15 per 1,000 per annum, and the decline over the entire period was 0.10 deaths per 1,000 of population per annum. The second, or what may be broadly called the

prohibition period, from 1921 to 1926, inclusive, presents a different picture. The mortality is on a much lower level than in the earlier years. The 6-year average death rate was 12.58 per 1,000; but, on the other hand, the trend of mortality (again indicated by the heavy straight line) is no longer downward. There is now a rising tendency, the actual rate of rise being 0.09 deaths per 1,000 per annum, or about as rapid an increase as was the decrease in the earlier and pre-prohibition period.

A somewhat different situation appears to have prevailed among the insured lives of the Metropolitan Life Insurance Company, as is shown in the lower part of Chart I. In this urban and industrial population, the average death rate between 1911 and 1917 was 11.81 per 1,000. The mortality declined 0.15 deaths per 1,000 per annum during this 7-year period. In the prohibition years, the average death rate was 8.71 per 1,000. But now we see a trend of mortality which is virtually unchanged, the decline being only 0.01 per 1,000, or 1 in 100,000 per year. This slight change has no significance whatever in view of the short period covered and the marked annual fluctuations of the rate from the average during the prohibition period.

How shall we interpret the figures on this chart? The first thing that comes to mind is the fact that the level of mortality in the prohibition years has been clearly lower than in the earlier years, both in the general population and among the insured. In the general population the average death rate between 1921 and 1926 was 16.9 per cent lower than in the earlier period. Among the industrial policy holders, the average death rate was 26.2 per cent lower in the prohibition period than in the earlier one. Do these lower average death rates, as some have claimed, measure the effects of the prohibition legislation?

Before such a conclusion can possibly be drawn, it must be remembered that long before the prohibition era we were already enjoying a declining mortality, which was thrown temporarily out of line by the influenza epidemic of 1918. The years 1919 and 1920 brought down the mortality rate to a point lower than it had ever been before, although both years had serious influenza outbreaks in the early months. The condition since 1921 appears to be merely a continuation of the downward tendency of mortality during pre-prohibition years, but with its acceleration retarded among the insured and entirely lost in the general population. And it is noteworthy that during these same years, the death rate in most European countries declined appreciably. Such improvement was not limited to those engaged in the World War but affected the countries of Europe almost without exception. The years since 1920 have been generally years of good and improving mortality.

CHART I—TREND OF MORTALITY, ALL CAUSES OF DEATH, 1900–1926, IN THE U. S. REGISTRATION STATES OF 1900; AND 1911–1926, METROPOLITAN LIFE INSURANCE COMPANY, INDUSTRIAL DEPARTMENT

DEATH RATES PER 1000

The effect of such a movement as prohibition on the death rate would be expected to become cumulative. It would certainly not show its fullest effect at the beginning. According to our figures, the most favorable year of the prohibition period, so far as the mortality of the general population is concerned, was in 1921. Since then, the death rate has been rising in the general population and has remained virtually unchanged among the insured. It might be argued that if prohibition were really a vital force in determining better health conditions, its influence would become more pronounced from year to year. This has clearly not happened in the population taken as a whole. If we had only these figures, the most favorable interpretation we could place upon them would be that the prohibition legislation had come into effect at a time of low and declining mortality and that it had had no appreciable effect in still further improving the mortality of our people.

But, fortunately, we have secured from the Census Bureau at Washington additional data which, supplementing those on insured lives, make possible a dissection of the mortality experience of the entire population into several classifications. The first of these is an analysis by sex and the second, by age. It is entirely possible that a negative result such as we have shown in our first chart may be a composite of conflicting tendencies in the several parts which make up the whole. This will be clearer as we proceed with the discussion of the additional material.

MORTALITY BY SEX

Chart II shows the same data as in Chart I, except that we may now distinguish between the two sexes in the general population and the two sexes for both white and colored persons among the insured. In the upper half of the chart, we see a sharp decline in the mortality among both males and females prior to 1917. From 1921 onward, there is a marked rise in the death rate among the males and a virtually stationary condition among the females. The slight decline of 0.03 per 1,000 per annum, in this sex, is of no significance. In the lower half of the chart for the insured lives, we find an interesting situation. The colored males show a rapidly mounting rate of mortality in the period between 1921 and 1926; among the colored females, the rate of mortality has likewise risen, but the rate of increase is much less than among the males. Among white persons, on the other hand, the males show a stationary death rate; while white females show a sharply declining death rate during the prohibition period. The actual decline among these white females was 0.12 per 1,000 per annum, and there can be no question as to the significance of the decline. In other words, the improvement in mortality during the period between 1921 and 1926,

CHART II—TREND OF MORTALITY, BY SEX, 1900–1925, U. S. REGISTRATION STATES OF 1900; AND BY SEX AND COLOR, 1911–1926, METROPOLITAN LIFE INSURANCE COMPANY, INDUSTRIAL DEPARTMENT.

which was shown in Chart I, was entirely limited to the group of white females. In the light of what we saw happen in the general population, we may safely conclude that there has been a different tendency in the mortality of males and of females during the prohibition years and that there has been a real improvement among white females.

MORTALITY BY AGE

Continuing our argument, we may now examine the mortality situation in the several age groups of the general population and among the insured. The facts are clearly shown in Charts III and IV. The first of these reflects the conditions in the general population of the registration states; the upper half presenting the facts for males, the lower half for females. Concentrating attention on the period 1921 to 1925, inclusive, we find that among males the death rate declined very sharply among children under age 5 and less sharply in the age periods 5 to 9 and 10 to 14. The facts are shown in the upper left hand panel. The age period 15 to 19 already shows a stationary condition in the mortality during the prohibition period and this continues until age 35, after which, each one of the age periods shows a rapidly increasing mortality during recent years. In the female sex, as shown in the lower half of the chart, the situation is slightly different. The declines are unmistakable in the early years of life and continue up to age 35. It is only after age 35 that the mortality decline among females is either retarded or is actually converted into a rising tendency.

Among the insured of the Metropolitan Life Insurance Company, virtually the same situation appears, as is indicated on Chart IV. The facts for white males are shown in the upper half of the chart; those for white females in the lower half. The decline among males from 1921 to 1926 is very sharp at the ages 1 to 4. It is less marked but significant in the age periods 5 to 9, 10 to 14, and 15 to 19. The age period 20 to 24 shows a slight decline. The period 25 to 34 shows no change. From age 35 onward, the death rates show a rising tendency during these prohibition years, and this becomes very marked at the advanced ages. Among the females, the declines are just as sharp in the early periods, that is, up to age 20. But unlike the males, the declines continue during the age periods 20 to 24 and 25 to 34. The rates remain virtually unchanged in the age period 35 to 44. The years 45 to 54 show an insignificant rising tendency and only the age period 55 to 64 shows a rise in the death rate.

We have, therefore, for the first time succeeded in converting a flat and negative composite into a rather interesting series of tendencies in the several component groups of the population, which may help us to

CHART III—TREND OF MORTALITY, 1900–1925, BY SEX AND AGE IN THE U. S. REGISTRATION STATES OF 1900.

CHART IV—TREND OF MORTALITY, 1911–1926, WHITE PERSONS, BY SEX AND AGE, METROPOLITAN LIFE INSURANCE COMPANY, INDUSTRIAL DEPARTMENT.

answer the question we have for discussion. For one thing, there is now much more agreement in the results of this two-sided investigation. We may summarize our findings as follows: That the prohibition period is characterized by sharply declining mortality rates among children and adolescents of both sexes; and that this decline is characteristic of a number of additional age periods among women. The improvement is retarded among young male adults and disappears altogether during the middle years of life in that sex. In fact, the mortality has definitely risen among men, after age 35. Altogether we may safely say that over half of the total population has experienced a very favorable mortality during recent years. One might even go a bit further and say that the facts are consistent with an assumption that the conditions of life during the period of the new legislation have been beneficial to this large part of the public. A little arithmetic will show that there has been a saving each year of about 14,500 children under age 5, another 2,000 each year between ages 5 and 10 and another 1,000 between age 10 and 20. This makes a total of approximately 17,500 young lives a year.

No one would assume that this gain was entirely the result of the new legislation for reasons we have already given. Many causes have undoubtedly operated to bring this favorable condition about. What some of these are will be made clearer if we examine into the diseases and conditions which have declined among women and children during the 6-year interval since prohibition came into effect.

At the children's ages, the greatest improvement in the death rate has taken place from accidents, from diarrheal diseases and from pneumonia. Infectious diseases have likewise declined considerably. Among young women, the improvement we spoke of is traceable somewhat to a decline in tuberculosis. There has also been a sharp decrease in the mortality from puerperal causes. It would appear, therefore, that the improvement is a response, in some measure, to the direct attack made by health and social service agencies both public and private which has been going on for years against the communicable diseases and against the diarrheal diseases of children. But, in addition, it may be considered a reaction to a rising standard of living, and this is especially evidenced by the lower tuberculosis and the lower pneumonia rates.

The whole picture is consistent with and may well be expected to have arisen (to an appreciable degree) from better conditions within the home, such as more and better food, better medical service and better housing. It is impossible to measure or to say how far any one factor has operated in the direction of reducing mortality. The increased facilities of public health work and the better conditions within the

home have operated together to produce the end result, and it would be entirely unfair to over-emphasize the effect of one of these forces as against the other. In fact, these two activities work best hand in hand and add to each other's effectiveness.

While we may say that the death rate of children and of young women, that is, those who remain at home for the most part, would probably have gone down without prohibition, it would be too much to assume that the conditions within the home during the prohibition years had not been instrumental in furthering the decline. The conditions of domestic life during the last few years have been such as to add incentive and power to the forces already at work to make for better health and longer life in these divisions of the population.

IMPROVEMENT IN ECONOMIC CONDITIONS

Evidence toward this conclusion, which is presented very tentatively, is afforded by the observations of the army of social workers, insurance agents and business men, who from one end of the country to the other are virtually in accord that the years since 1920 have seen an improvement in the economic condition of the homes of the great mass of American people. Never before have savings deposits been so great or have life insurance policies been added to and maintained as during the last 6 years. Retail trade has never experienced such prosperity. All of this emphasizes what is universally observed, namely, that the housewife now has more money to spend on the necessities of the household, on food, on clothing, and on shelter to a degree that has never before been possible for so many. It has been suggested that that part of the wages which under the old régime went into the liquor traffic is now largely diverted into channels which mean increased protection and welfare for the family. But this phase of the subject is unfortunately beclouded with much uncertainty. We know very little that is accurate with reference to the amount of alcohol now being consumed, what is being spent for it, and least of all how the facts shape up for the various economic levels of the population.

RISE IN MALE DEATHS DUE TO ALCOHOLISM

How then does our assumption with regard to women and children tie up with the facts we have given for the condition among men? Why have the death rates for men increased in view of these favorable changes? In that sex, we find that an improvement in tuberculosis has gone hand in hand with an increase in the mortality from pneumonia, from accidents, from heart disease and kidney disease. During this period, there has been a constant rise in the death rate from alcoholism

and from the associated condition of cirrhosis of the liver. Both of these diseases were at a minimum in 1920. They are now at a point almost as high as in the decade prior to prohibition. The picture we have found to exist in the mortality of adult men in the United States is entirely consistent with the observations universally confirmed of a continued widespread indulgence in alcoholic beverages by men. Prohibition has not been particularly effective in that sex and especially has this been true in the cities and, more particularly, in the eastern states.

If the saloon has gone and the great body of men no longer spend a large part of their wages on liquor, it is only too clear that what they do drink now, even if in smaller quantities and at a lesser total cost, is of such a deleterious character, as to result in no advantage to their health. The quality of liquor used throughout the country is sufficiently bad to make up for the smaller quantity consumed. The economic gains help us to understand the condition among women and children; the character of the present supply of liquor helps us to understand the lack of improvement which appears in the mortality of men.

There can be little question as to the unsatisfactory situation now confronting large areas of the country as regards the use of alcohol by men. Beginning with 1920, there has been a continuous and marked rise in the number of deaths resulting from the use of alcohol. In 1920, the death rate from this condition reached its minimum, namely, 1.3 per 100,000. Every year since then, virtually with no exception, has seen a rise and the rate is now more than three times as high as it was only 6 years ago.

The same condition is found to exist among the industrial classes as among those of larger incomes whose insurances are carried in the ordinary departments of the insurance companies. The insurance results are confirmed by the population figures for the several states and this phenomenon is widely observed, larger states showing more strikingly what can be found in the smaller ones with a little more searching. In Maryland, the alcoholism death rate in 1926 was the highest ever recorded since 1911. In Rhode Island, Michigan and New York, the 1926 rate was the highest with a few exceptions.

The records of hospitals for the insane tell a similar story. The year 1920 showed the lowest rate for admissions to hospitals for mental disease due to alcoholism. Since that year, the admission rate has increased step by step and last year saw conditions three times as bad as 6 years ago. It is only too true that in the country over, with very few exceptions, there is a mounting rate from alcoholism and from the associated diseases among the male population.

This situation is in striking contrast with what has occurred in

neighboring Canada. In the Dominion, likewise, several provinces have been experimenting with one form or another of regulatory legislation. But in that country, there is as yet no evidence of any untoward result in the mortality rates for any large group of the population. The experience of the Metropolitan Life Insurance Company in Canada is especially instructive. Among over 1,000,000 policyholders, there have been recorded only 100 deaths from alcoholism and acute alcoholic poisoning during the entire period, 1911 to 1926. On the annual basis, the number of deaths from these causes among Canadian policy holders is so small as to be almost negligible. The death rate from these causes, in fact, is only about a quarter of what it has been among insured lives in the United States. But what is even more interesting is the fact that the deaths from alcoholism have gone down during the last 10 years in Canada—a condition very different from that in the United States. In so far as death rates are a reliable indication, the Canadians seem to have succeeded much better than we in their efforts to control the problem of alcohol and of alcoholism.

DEGENERATIVE DISEASES IN THE UNITED STATES

But there must be no misunderstanding of the true import of these findings. The death rate from alcoholism alone is not high. Deaths from alcoholism and from alcoholic insanity are only a small part of the total. These figures are important not so much on their own account but rather as indications of a condition or habit of life which now prevails. Much more important than the deaths from alcohol are the deaths from the degenerative diseases such as, heart diseases, kidney disease and pneumonia, which are apparently on the rise. Just how far the indulgence in alcohol will explain these increases, it is impossible to say. But, in any case, there is no indication as yet of a tendency toward improvement in these among American men.

EFFECTS OF PROHIBITION NOT UNIFORM

The effect of the prohibition legislation on the public health has clearly not been uniform among the various groups of the American population. This fact probably explains much of the confusion which has existed in the public mind with respect to the influence of prohibition. Many persons have thought of prohibition as if it were a definite and unvarying condition. The facts are very different. Absolute prohibition prevails hardly anywhere and affects as yet only small numbers of people.

We must learn to think of the force of prohibition as varying to a greater or lesser degree with geographical areas, with economic strata

and with the sex and age classes of the population. It is only when considered in this light that we can hope to obtain a consistent answer to our initial question. We may then say that the effect of the prohibition situation on the public health has probably been good where there has been prohibition to an appreciable degree, and the situation has been unsatisfactory to the degree in which there has in fact been no prohibition. Especially is this true in those areas of the country and among those classes of the people where there has been drinking of the highly deleterious stuff that passes for alcoholic beverages these days. Such a conclusion is at once consistent with the facts at our disposal and squares with what has generally been accepted as the true relation existing between heavy alcoholic indulgence and individual health.

This conclusion must not be interpreted, however as an endorsement of the 18th Amendment and of the current enforcement law. This paper is not concerned with the desirability of this type of legislation. Our main purpose has been to discover the facts with regard to the health of our people during recent years. We have disclosed, we believe, certain facts which throw light on the current situation. If it were desired fully to evaluate the prohibition legislation, it would be necessary in addition to these facts on health to consider other items of equal importance in the life of the nation, each one of which would require careful study. The effect of the recent legislation upon public honesty, respect for law and the integrity of public officials, as well as other considerations, will have to be considered with great care. Much time must elapse before these important questions can be considered adequately in the light of the new legislation.

The National Committee for the Prevention of Blindness Annual Meeting

WITH Hon. William Fellowes Morgan, President of the National Committee for the Prevention of Blindness, presiding, the Thirteenth Annual Meeting of the National Committee took place at The Russell Sage Foundation Building, 130 East 22nd Street, New York, N. Y., Thursday, December 15, at 4:30 P. M. Dr. Park Lewis, of Buffalo, Vice-President of the National Committee, and for many years a student of international aspects of saving sight, spoke on: "Prevention of Blindness: A World-wide Problem."

Beginning January 1, 1928, the Committee will be officially known as The National Society for the Prevention of Blindness.

"The Common Cold"

Etiology, Prevention and Treatment*

VOLNEY S. CHENEY, M. D., FELLOW A. P. H. A.

Medical Director, Armour and Co., Chicago, Ill.

IN ALL industries absenteeism on account of sickness is a serious economic problem. In a recent report of the Boston Edison Company covering a period of 10 years, the absences per year on account of sickness were 8.9 calendar days for males and 14 days for females. Among males, sickness caused 12 times as much absenteeism as accidents and the ratio for females was 171 to 1. Respiratory diseases caused nearly one-half of the total number of days lost by men. Out of every 10 men, 4 lost time during the year on account of "common colds." Out of every 10 women, 7 lost time on account of the same cause. Males lost 1.4 days per year and females 2.1 days per year because of colds. Based upon this average, the economic loss caused by "colds," in wages alone, in all the industries of the United States is several millions of dollars and when we also consider the losses due to decrease in efficiency, decrease in production, and the extra expenditures of the invalid, the total is enormous.

There is no medical subject which has greater interest for civilized mankind than that of the "common cold." My experience of many years among the aborigines of the Southwest convinces me that colds, as we know them, are a product of civilization. The layman uses the term "a cold" to cover a multitude of conditions which even the medical man does not always differentiate; viz, an acute coryza; rhinitis; pharyngitis; laryngitis; bronchitis; la grippe; influenza and sometimes tonsillitis.

RESEARCH WORK MEAGRE

There has been a dearth of research work in the etiology of colds, except in an endeavor to prove the theories that a cold was either a primary infection by one or a group of bacteria, or due to a filtrable virus. This lack of research work must be due to the fact that a cold is ordinarily considered a rather trivial affair and one which does not respond readily to treatment but runs its natural course; it cannot be

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

due to the apparent economic unimportance of a cold, for statistics show that about 45 per cent of absenteeism in most of our large industries is caused by colds or their sequelae. Where it does not cause absence from work, it materially affects a person's efficiency and, in that way, effects also a great economic loss.

The accepted definition for "a common cold" has been "an acute infection of the nasal and pharyngeal regions, or of the upper respiratory tract"; but no one has been able to demonstrate that any one of the many bacteria normally inhabiting the nasal, buccal and pharyngeal cavities, is the cause of a cold, nor has it been conclusively proved that a group of bacteria is responsible for the symptoms we call "a cold." The infectious origin of a cold is only an unproven theory, and a theory based upon a false premise because in the early stages of a cold the secretions from the nose are always sterile and the organisms usually regarded as being the causative factor are only *secondary invaders* of the latter stages.

Another theory as to the etiology of colds is that of a filtrable virus as brought forth by Kruse in 1914, but this theory was also definitely demonstrated as being untenable through a series of experiments by Robertson and Graves in 1924.

The *International Medical Digest*, January, 1927, says:

Summarizing the present knowledge of the bacteriology of common colds, one must say that, as yet, there has not been found any specific organism that can be considered as the etiological factor. The possibility of a filtrable virus as a specific cause for rhinitis is interesting but, up to the present time, the evidence is too conflicting to accept it as a fact.

It soon becomes apparent that for a proper evolution of the causes for colds, one must go further than the study of the bacteria in the upper respiratory tract.

That is just what I have been doing in my study of colds—going beyond the study of the bacteria in the upper air passages and seeking a systemic disturbance of which the syndrome of a cold is only a local manifestation.

I have never been thoroughly satisfied that a cold was only a trivial affair and was primarily an acute infection of the upper respiratory tract. For the past 11 years, I have been making an intensive study of colds, their etiology, their course, both with and without treatment, and the after results or sequelae.

COLD IS NOT INFECTIOUS

The first thing that I want to oppugn is that "a cold is an acute infection." I have been able to disprove this by experiments on a number of people free from cold by trying to inoculate them with the secretions of an individual suffering from an acute cold. As infectious dis-

eases are generally most contagious in the period of incubation or the early stages, I chose the time when the secretions were most profuse for my inoculations. In no single instance was a cold contracted.

If a cold were an acute infection, its origin or source could nearly always be definitely traced; but this is rather a hard thing to do and it is generally turned off with the remark, "I must have been exposed to a cold somewhere." It is true that a cold will frequently run through families and through offices where the clerks are closely associated, but this does not prove that a cold is spread by contact with other persons. These individuals, in the home and in the office, are subjected to the same unhygienic conditions of environment, and those conditions are the factors in bringing about an altered metabolism and a systemic disturbance affecting all the fluids and secretions of the body.

EFFECT OF CLIMATIC CONDITIONS

Climatic conditions have always been held responsible in some way for colds. Inclement weather conditions—of which the chief are severe cold, dampness, windiness, or sudden change of temperature—are frequently considered the exciting or at least a contributory cause of colds. The incidence of colds is generally greatly increased in the winter months and cold weather. Many observers have tried to explain why colds should be more prevalent in cold weather, and the theory most frequently advanced is the disturbing influence of cold upon the heat-governing center, through the autonomic nervous system; but the physiological function of the heat regulating center is to adapt the organism to frequently changing climatic conditions, and in health its regulating function is not easily disturbed.

During the winter months, we lose a part of the actinic effect of the ultra-violet rays of the sun because of its southern declination requiring the rays to pass through a thicker stratum of atmosphere which, especially if smoke-laden, acts as a filter to the rays and materially decreases their chemical action upon the blood, chiefly influencing its calcium content or calcium fixation.

Climatic variations are a contributing factor only so far as they inhibit our normal activities and decrease our utilization of protein foods which are always in excess of what we normally require. We eat too much and exercise too little in cold weather. Colds are less frequent in warm weather because we eat less of high protein foods and exercise more. A lumber camp in which I spent several years and where the men were exposed to all kinds of weather and sub-zero temperature, was particularly free from colds and respiratory diseases. I do not consider cold, *per se*, as an etiological factor.

The times of the greatest incidence of colds in our industry is on Mondays, days following holidays, and days following banquets or parties where there is an abundance of good things to eat. I have also observed that colds are very prevalent in our traveling salesmen and others who are on the road a great deal. While traveling there is a decided change in daily routine compared to the one maintained while at home, a proneness to overeat, drink too much alcoholic stimulants, an increased mental strain, irregularity of the bowels, lack of proper exercise, and loss of sleep. Fatigue, no matter how it is acquired, is a very important factor, and the reason for this is the altered metabolism of the blood and tissues which it produces.

What are the symptoms of a common cold? They vary with the severity of the attack. In a moderately severe one they are coryza, nasal and pharyngeal irritation, headache, muscle-ache, lassitude, anorexia, and malaise. These are also the symptoms of two widely divergent systemic disturbances, one of which is very prevalent and frequently diagnosed—the other is rather rare.

In a study of several thousand cases of colds extending over a period of 11 years, and after numerous unsuccessful attempts to inoculate cold-free persons with the secretions from acute colds, I am thoroughly convinced that an acute cold affecting the upper respiratory tract is not primarily an infection but only a symptom syndrome of a systemic disturbance.

A number of cases of colds of varying severity were carefully studied in the laboratory. Observation was made as to the degree of acidity of the urine; the CO_2 combining power of the blood as an indicator of the alkaline reserve; tests were also made to determine the calcium content of the blood, the sugar content; non-protein nitrogen and the basal metabolism. The urine invariably carried a higher degree of acidity than the normal—in some cases as high as 80° (normal 35°); the CO_2 combining power of the blood in all cases was low, the highest being 52 per cent; the sugar content of the blood was generally decreased (below 100 mg. per 100 c.c.); the metabolic rate was always on the minus side. (These cases were carefully selected because of their lack of any symptoms of disturbed thyroid activity.)

SUMMARIZING FINDINGS

There is a change in the blood chemistry and, consequently, there must be a change in the tissues supplied by the blood. There is a decrease in the bicarbonates or reserve bases contained in the blood plasma and the tissues, notably in that of the sodium and calcium salts; and an increase in the bicarbonate tolerance as determined by Sellard's

test. There is also a change in the activity of the thyroid gland, manifested by a decrease in the metabolic rate; a slight decrease in the sugar content of the blood with a slight retention of non-protein nitrogen. The secretions of the nose and throat are found to be less alkaline than the normal, sometimes having a decidedly acid reaction to litmus paper.

These findings seem to point the way to the conclusion that a cold is a local manifestation of a systemic disturbance; namely, a disturbance of the alkaline balance or reserve, in other words, a mild acidosis, or perhaps better stated, a lessening of the "buffer" action of the blood plasma through a decrease in its bicarbonate content. This conclusion is strengthened by treatment in which thorough alkalization will always abort and cure a cold—a radical statement but nevertheless true, provided the treatment is thorough.

INDUCING ACIDOSIS

I have been able to induce all the symptoms of a cold, in varying degree from a simple coryza to that of la grippe and the "flu," by the induction of an artificial acidosis through the administration of ammonium and calcium chlorides. The degree of severity of the symptoms was in direct ratio to the degree of acidosis induced. In the severer degree of acidosis, all the classical symptoms of the "flu" were present, even including a low degree of fever. The symptoms rapidly subsided upon the administration of sodium bicarbonate in large doses by mouth and by rectum.

AN ABORTIVE TREATMENT

If the disease is attacked when there is a beginning dryness in the pharynx or a slight coryza, or congestion of the mucous membrane of the nose, and alkalization is instituted by large doses of sodium bicarbonate, until the urine is alkaline to litmus paper, a "cold" can always be aborted. Along with the sodium bicarbonate which I generally prescribe in 60 g. doses, accompanied by a large glass of hot water, every 2 hours for 3 doses, I give to an adult 1 g. of calcidin (a calcium and iodine combination) every half hour until 6 doses have been taken.

Most colds begin to manifest themselves late in the afternoon or early evening and the abortive treatment is best given at this time up to retiring. At the time of taking the treatment, the usual meal should be dispensed with, or should consist of milk and some cereal, or soup or broth. If the bowels are constipated, they should not be moved by a cathartic or laxative but the lower bowels should be relieved by a soap suds enema. This treatment will abort colds, if taken in their incipency.

Where a cold has advanced to the stage where there is a hoarseness and a profuse coryza, or where this condition has advanced to what we generally term "a cold," I use the following treatment:

Initial dose 60 g. of sodium bicarbonate and 1 g. of calcidin, then 30 g. of sodium bicarbonate and 1 g. of calcidin every 2 hours for 6 doses, then 20 g. of sodium bicarbonate with $\frac{1}{3}$ g. of calcidin every 3 hours during the waking period until the cold is checked. The administration of the sodium bicarbonate should always be in or followed by a large glass of hot water. Locally, spray the nose and throat with a 1 to 5000 solution of metaphen, or other alkaline solution (1 dram of sodium bicarbonate to one pint of water) morning and night. If the bowels are constipated, I prescribe no laxative or cathartic but use an enema of soap suds to relieve the lower bowels.

Prophylaxis is best maintained by exercise and a diet which is well balanced and thoroughly adapted to the individual's physical activities.

CONCLUSION

Colds and their sequelae including rhinitis, pharyngitis, laryngitis, bronchitis, la grippe, influenza, and pneumonia are not infectious, as we generally consider a disease to be infectious, but are due to a disturbance of the alkaline reserve or balance (acid-base equilibrium). The more severe the degree of disturbance, the more serious the disease.

Conditions capable of producing a mild acidosis or disturbing the "buffer" action of the blood plasma, are contributing factors in producing a cold: a poorly balanced diet, lack of exercise, fatigue, constipation, and infections anywhere in the body. Colds can be prevented by maintaining the alkaline balance through proper diet, exercise, and the careful use of sodium bicarbonate or alkaline waters.

Colds can be aborted by administering sodium bicarbonate in doses large enough to thoroughly alkalinize the system together with small doses of calcidin or iodine and calcium.

Colds can be cured by the administration of the same drugs in smaller and frequently repeated doses.

DISCUSSION

Dr. Wade Wright called attention to Dochez's study of colds in some 40,000 persons. This showed distinct seasonal peaks, the highest late in winter, with the next highest in the fall. These peaks occurred on the Pacific coast the same as in New York City and without relation to temperature changes.

Dr. Emory W. Sink noted that after a football game at Michigan University there were invariably more colds than usual. Was this due to fatigue or to exposure? It has been shown that colds lasted on the average two days longer if cathartics were given. Yet there was something in the psychology of giving medicine of some sort. His general opinion was that there was some contact infection in the production of widespread colds.

Mr. Massey of the Pennsylvania Railroad Company declared that the common

cold was enormously costly to the railroads of the country and that anything that would help in control would be eagerly accepted.

Dr. Robert A. Kehoe considered that with the common cold the most important things were its ubiquity and its sequelae. Certainly the final factor is a germ or organism. It is not proved that some systemic condition precedes the invasion by the organism. Yet what does produce this sudden upset? How do we account for the sudden colds that come out of a clear sky?

Dr. Otto P. Geier was impressed with the frankness and boldness of this paper. He felt that our research investigations in the subject of colds had been getting too far away from the clinical observations; that too much scientific work of this sort is going on—so much as to be indigestible—with the practicing physician left out. The industrial physician has an excellent opportunity for clinical research in the question, and he suggested that others try out Dr. Cheney's methods. He was discouraged with the work of the specialists in the field of the common cold and suggested that industrial physicians discourage the sending of workers afflicted with colds to the specialists. When they do send them the colds usually last two or three days longer. Mondays have always been the worst days for colds, but "blue Monday" is not so bad today as it used to be.

Dr. Alice Hamilton called attention to the experimental work of Mudd and Grant of St. Louis who showed that an actual blanching of the mucous membranes of the nose and tonsils takes place with a chilling of the body. This seemed to be definite proof of primary physical influence.

Dr. A. J. Lanza stated that a prominent industrial physician at a plant employing 10,000 people had tried out argyrol instillations for colds, using controls. He had the patient lie with his head hanging over the end of a table. Argyrol was instilled by the use of a U tube. This plan of treatment was carried out over a long period of observations with generally disappointing results. In fact the patient so treated retained their colds longer than those not so treated.

Dr. Silverman, of Syracuse, did not believe that immunity lay in the question of H-ion equilibrium. The idea of curing colds by disturbing this equilibrium with sodium is too simple. Certainly contact must be recognized as a chief mode of spread and definite causative organisms must be recognized.

Dr. Frank L. Rector stated that certain Australian physicians had noted a sequence in the common cold from the condition of blanching to mucus-excess which exudate produced a favorable culture for the growth of bacteria. Such events supported the common opinion of a predisposed state followed by an invasion of micro-organisms.

Dr. Julius Levy, pediatrician, pointed out that practically all diseases in children were associated with an acidosis. This was true for the gamut of epidemic diseases such as pneumonia, measles, etc. This acidemia should be treated by itself and could not be considered the basic cause of colds, but simply a product.

Dr. Cheney, in closing, stated that the whole theory of infection in relation to immunity must be rearranged. He has had very favorable results in treating scarlet fever with large doses of alkalies. The whole question is a big field for the physiological chemist. In some experimental work he had produced typical influenza in 5 cases by administering calcium chloride and ammonium chloride, and had then promptly cured the condition by alkalization. He did not deny that an invading organism was a later factor in the common cold, but he had found that the blood changes recorded in his paper were all present before infection began.

Figure 1

Artificial Respiration By the Prone Pressure Method*

1. Lay the patient on his belly, one arm extended directly overhead, the other arm bent at elbow and with the face turned outward and resting on hand or forearm so that the nose and mouth are free for breathing. (Fig. I.)

2. Kneel, straddling the patient's thighs with your knees placed at such a distance from the hip bones as will allow you to assume the position shown. (Fig. I.)

Place the palms of the hands on the small of the back with fingers resting on the ribs, the little finger just touching the lowest rib, with the thumb and fingers in a natural position, and the tips of the fingers just out of sight. (Fig. I.)

3. With arms held straight, swing forward slowly so that the weight of your body is gradually brought to bear upon the patient. The shoulder should be directly over the heel of the hand at the end of the forward swing. (Fig. II.) Do not bend your elbows. This operation should take about 2 seconds.

4. Now immediately swing backward so as to completely remove the pressure. (Fig. III.)

5. After 2 seconds, swing forward again. Thus repeat deliberately 12 to 15 times a minute the double movement of compression and release, a complete respiration in 4 or 5 seconds.

6. Continue artificial respiration without interruption until natural breathing is restored; if necessary, 4 hours or longer, or until a physician declares the patient is dead.

* The method and pictures have been approved by:
American Telephone & Telegraph Co.
American Red Cross
American Gas Assn.
Bethlehem Steel Co.
National Electric Light Assn
National Safety Council

Bureau of Medicine & Surgery, Navy Dept.
Office of the Surgeon General, War Dept
U. S. Bureau of Mines
U S. Bureau of Standards
U S Public Health Service

*Figure II**Figure III*

7. As soon as this artificial respiration has been started and while it is being continued, an assistant should loosen any tight clothing about the patient's neck, chest or waist. *Keep the patient warm.* Do not give any liquids whatever by mouth until the patient is fully conscious.

8. To avoid strain on the heart when the patient revives, he should be kept lying down and not allowed to stand or sit up. If the doctor has not arrived by the time the patient has revived, he should be given some stimulant, such as one teaspoonful of aromatic spirits of ammonia in a small glass of water or a hot drink of coffee or tea, etc. The patient should be kept warm.

9. Resuscitation should be carried on at the nearest possible point to where the patient received his injuries. He should not be moved from this point until he is

breathing normally of his own volition and then moved only in a lying position. Should it be necessary, due to extreme weather condition, etc., to move the patient before he is breathing normally, resuscitation should be carried on during the time that he is being moved.

10. A brief return of natural respiration is not a certain indication for stopping the resuscitation. Not infrequently the patient, after a temporary recovery of respiration, stops breathing again. The patient must be watched and if natural breathing stops, artificial respiration should be resumed at once.

11. In carrying out resuscitation it may be necessary to change the operator. This change must be made without losing the rhythm of respiration. By this procedure no confusion results at the time of change of operator and a regular rhythm is kept up.

Race Betterment Conference

THE Third Race Betterment Conference will be held at Battle Creek, Mich., January 2-6. The object of the conference is to gather the facts of race degeneracy and of recent scientific progress, in the prolongation of human life and to give a greater impetus to the dissemination of these facts for the benefit of humanity. Progress will be reported in the field of bacteriology, medicine, nutrition, eugenics, physiology and education. The conference is being organized under the auspices of Race Betterment Foundation of which John Harvey Kellogg, M.D., is founder and president, and headquarters will be at the Battle Creek Sanitarium. Dr. C. C. Little, president of the University of Michigan is head of the Conference Committee, which also includes Dr. Max Mason, president of the University of Chicago, and Dr. Glenn Frank, president of the University of Wisconsin; Haven Emerson, M.D., Director DeLamar Institute of Public Health, Columbia University.

Among the speakers will be Herman N. Bundesen, M.D., president of the American Public Health Association; Louis I. Harris, M.D., City Health Commissioner, New York, N. Y.; Frederick L. Hoffman, Consulting Statistician, Prudential Life Insurance Company, Newark, N. J.; E. O. Jordan, chairman Department of Hygiene & Bacteriology, University of Chicago; Guy L. Kiefer, M.D., Michigan State Health Commissioner; A. T. McCormack, M.D., Secretary, Kentucky State Board of Health; Mary Swartz Rose, Ph.D., Professor of Nutrition, Teachers College, Columbia University; William Alfred Sawyer, Medical Director, Eastman Kodak Co., Rochester, N. Y.; William F. Snow, President, National Health Council, New York, N. Y.; John Sundwall, M.D., Professor of Hygiene and Public Health, University of Michigan; Harvey W. Wiley, M.D., Washington, D. C.; and Henry F. Vaughan, City Health Commissioner, Detroit, Mich.

Definition of Stillbirth*

IN 1908 the Vital Statistics Section of the American Public Health Association adopted certain Rules of Statistical Practice. Rule No. 19, adopted at that time is:

No child that shows any evidence of life after birth should be registered as a stillbirth.

In 1913 the Vital Statistics Section adopted the following:

RESOLVED, that the present Rules of Statistical Practice relating to stillbirths and premature births as adopted by the American Public Health Association in 1908, should be strictly followed by American registration offices, it being understood, in Rule No. 19, "No child that shows any evidence of life after birth should be registered as a stillbirth," that the words "any evidence of life" shall include action of heart, breathing, movement of voluntary muscle.

So far as is known to the members of this committee, American statistical offices have been strictly observing this rule as amended by the resolution, except that the Province of Quebec has determined the fact of life after birth solely by the act of breathing.

The Health Section of the League of Nations has proposed the following definition of stillbirth, which has been referred to this committee:

A dead-birth is a birth of a foetus after twenty-eight weeks pregnancy in which pulmonary respiration does not occur; such a foetus may die either: (a) before, (b) during, or (c) after birth, but before it has breathed.

The Netherlands and the British Governments have refused to accept it, on legal and scientific grounds.

The proposed definition contains two very distinct propositions. Let us consider these two propositions separately:

First. The desirability of establishing a minimum period of utero-gestation.

Second. That breathing shall be the only acceptable evidence of life to distinguish a live birth from a dead birth.

PERIOD OF UTERO-GESTATION

The very glaring lack of uniformity in stillbirth statistics is found in the period of utero-gestation required as a minimum. In the United States this varies from the requirements of the State of Maryland (all products of conception), to that found on the Statute of the State of Washington (advanced beyond the 7th month of utero-gestation). Many of the state laws, however, have followed the recommendations

* Report of the Committee to Consider the Proper Definition of "Stillbirth," presented to the Vital Statistics Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 17, 1927.

of the Model Law and call for stillbirth reports if the foetus has advanced to the 5th month of utero-gestation.

League Statement—The communication from the Health Organization of the League of Nations, dated April 1, 1925, on page 2 states:

(c) Viability.—In proposing that a gestation of not less than seven months (twenty-eight weeks) shall be the term of development required for a "viable" foetus, the Committee has had in mind the very great difficulty of rearing an infant born after a shorter period of gestation. It is hardly too much to say that the survival of an infant born before the end of the twenty-eighth week of pregnancy is an event worthy of special record. It is rare, except when special facilities—e.g.: provision of an incubator—are available. The adoption of the Committee's proposal will not mean that the birth, at an earlier stage of gestation, of a foetus in which pulmonary respiration becomes established is not to be regarded as a "live-birth" (as hereafter defined); but it will mean that a birth before the end of the twenty-eighth week of pregnancy of a foetus in which respiration is not established is not to be counted as a "dead-birth" but as a "miscarriage" (abortion).

Where registration as a dead-birth is required in the case of a shorter gestation than twenty-eight weeks—e.g.: Switzerland (six calendar months), Japan (four months)—the adoption of the Committee's proposal need involve no change in legislation. In such instances, only those births which take place after the twenty-eighth week of gestation should be included in the principal (international) tabulation. Supplementary tabulations for national purposes could be given, showing the number of births occurring after gestations shorter than twenty-eight weeks.

Now, an examination of medical literature reveals many cases where a child born from the 18th to the 28th week has survived, even for years, and Taylor in *Principles and Practice of Medical Jurisprudence*, March, 1905, Vol. II, page 49, says:

Viability—According to the English law, it is not necessary that a child, when born, should be capable of living, or viable, in order that it should take its civil rights. Thus, it may be born at an early period of gestation; it may be immature and not likely to survive; or again, it may be born at the full period of gestation, but it may be obviously labouring under some defective organization, or some mortal disease, which must necessarily cause its death within a short time after its birth.

Fortunately, these points are of no importance in relation to the right of inheritance: an English medical jurist has only to prove that there was some well-marked physiological sign of life after birth ("Live Birth"); whether the child were mature or immature, diseased or healthy, are matters which do not at all enter into the investigation. It may at first sight appear to be inconsistent with justice that a child which is born immature or labouring under disease, owing to which it can not long survive its birth, should possess the same rights of inheritance as one which is born mature and perfectly healthy; but this evil to society is of far less magnitude than the adoption of a system which must constantly lead to subtle casuistical distinctions, and thereby create error and confusion. So long as there is no well-defined line between a child which is considered capable of living and one which is not, gross injustice must necessarily be inflicted by any rule of law similar to that which is admitted in the French Code.

Without going further into the medico-legal aspects of the question, it is very evident that the French Code differs from the English Code

and that probably the best thing for our section to do is to keep out of the fight and to allow the jurists to thresh out the legal tangle regarding viability.

Census Bureau correspondence shows that 20 years ago, in 1907, careful consideration was given to this subject by Dr. Cressy L. Wilbur. Please note that Rule 16 of the Rules of Statistical Practice was adopted by this section the following year, 1908. This rule 16 reads:

Statement of viability or nonviability of an infant prematurely born shall not be considered in classification.

In view of the existing Rule of Statistical Practice and in view of existing evidence and medico-legal opinions, there seems to be no sufficient reason for urging that the question of viability be considered in the definition of either "dead birth" or "live birth." Moreover, if live births occur before 28 weeks of utero-gestation, it would be unwise to urge that stillbirths before that period need not be reported, for not only is the relationship between live births and stillbirths of each period of utero-gestation a matter of increasing interest and importance, but the lack of necessity of reporting stillbirths before 28 weeks of utero-gestation would make infanticide of premature infants easy to conceal.

The time of quickening is usually given as the 18th week, and the 18th week begins on the 120th day. There is one case of record where a child born in the 18th week was alive at the age of 9 years. As all of these facts center about the 120th day, it seems the logical thing to do to maintain the wording in the Model Law that a stillbirth need not be reported unless it has advanced to the 5th month (i.e., until after 120 days).

The conclusions of your committee are therefore:

1. That Rule of Statistical Practice No. 16 should be reaffirmed.
2. That inasmuch as every live birth, of any period of utero-gestation, should be reported, every stillbirth which has advanced to the 5th month (after 120 days of utero-gestation) should be reported, and that states should carefully consider asking for reports for still earlier periods, as Maryland does today.
3. That the principle implied in the quoted paragraphs of the communication from the League of Nations be endorsed where it suggests that tabulations of stillbirths for international comparisons be made in the various countries for comparable periods of utero-gestation.

The second portion of the proposed definition of stillbirth offered by the League of Nations relates to the evidence of life after birth. It is based upon the hypothesis that the product of conception is a foetus until it breathes. In the propaganda accompanying this definition of stillbirth the accepted definition of birth is unchanged, and it is admitted that a child's heart may beat for some time after birth without efforts at breathing.

This portion of the definition must be considered from the three standpoints of statistics, science and law.

I. STATISTICAL ASPECT

Gross Statistics—If the proposed change would have any effect in modifying vital statistics in general it must be seen in the increased number of stillbirths recorded, and making a corresponding reduction in the living birth record, and the birth rate. It would also decrease the record of infant deaths and infant death rate. Because the number of infant deaths is less than that of births, proportionally the reduction will be greater in deaths than in births. Since infant mortality is computed according to the number of living births, the final result would be a seeming reduction of infant mortality. Manifestly, except where the number of births is very small, this apparent reduction of the infant mortality rate would be exceedingly small. Similarly, except where the population is very small, the reduction in general mortality rate would be infinitesimal.

Because the total number of stillbirths is only a fraction of the total number of births, the most apparent statistical change occasioned by such an alteration of rule would be in the increase of the stillbirth rate. Practically, the results of such an alteration of rule would be negligible, because heartbeat or movement of voluntary muscle is seldom observed when no efforts at breathing have been found.

Confusion and Lack of Exactness—If "breathing" alone, irrespective of degree, is to be the determining factor as to live or dead births, individual interpretation of the expression by physicians and others will create a variation in reports. This is illustrated by two actual examples. In one case the child lived 30 minutes, according to the record, and the physician reported: "This child only breathed four times after it was born. I think it got some of the amniotic fluid into its lungs and choked to death." In another case the record showed that the child lived 2 minutes. "Respiration was feeble." Strictly, these cases should both be reported as live births, but under the proposed evidence of *breathing only*, would not physicians feel justified in reporting them as stillbirths? Did these children breathe, or did they only attempt to breathe?

Changes to be Expected in Birth Rates, Death Rates, and Infant Mortality Rates if the League of Nation's Definition of Dead Births were Adopted in the United States—In the Boston Lying-in Hospital in 1926 there were 1,741 live births; 11 of these infants died within 30 minutes. Of these 11, 4 breathed and 7 did not, i.e., 63 per cent of those who died within 30 minutes did not breathe. These figures indicate that 0.4 per cent of children born alive do not breathe and that the League of

Nations' definition would lower the birth rate 0.4 per cent. Now, of deaths under 1 year about 4 per cent are deaths under 30 minutes and 63 per cent of 4 per cent is about 2.5 per cent; so that an estimate may be made that the League of Nations' definition would lower the infant mortality rate 2.5 per cent. Similar calculations indicate that this same definition would lower the general death rate 0.3 per cent.

These small changes in the birth and death rates are not impressive when we know that errors from 5 to 10 per cent due to defective registration are not uncommon.

The corrective factors indicated are so small that we may conclude that the birth, death, and infant mortality rates of the various countries will be reasonably comparable even though there be no uniform definition of the word *dead born*. As a matter of fact the corrective mortality factors already indicated for the new definition are probably three times larger than they should be, for, to queries sent out by the Census Bureau, satisfactory replies were received from physicians regarding 538 children who died within the first 30 minutes of life, and of this number 433 breathed and 105 did not; i.e., only 20 per cent of those who died within 30 minutes did not breathe.

From the broader standpoint of vital statistics, therefore, the proposed change does not appear to be necessary to make our statistics harmonize with those of countries working under the proposed rule.

II. SCIENTIFIC ASPECT

Neither is the proposed change in definition clearly indicated by present scientific knowledge.

Definitions and Evidence—The term stillbirth or dead birth has universally been recognized as meaning dead at the moment of birth. Death means absence of life. As generally recognized, the status of foetus terminates with birth, provided that the organism is alive at time of birth.

Life of an animal is shown by heart-beat, respiration or movement of voluntary muscles. This is general, and it applies to adults as well as to new-born children.

The report of the Committee of the Royal Statistical Society on stillbirth makes no reference to breathing, but gives as the sole evidence "whose heart has ceased to perform its functions before the whole of the body of such child has been completely extruded from the body of the mother."

The definition offered at the meeting of the International Institute of Statistics in 1913 also makes no mention of breathing, but is based upon "absence of pulsations in the cord, and absence of heart sounds or impulses."

It is chiefly heart-beat upon which physicians today depend for determination of fact of intra-uterine life. Why should it be ignored as evidence of life after the child has been born?

It is well known that it occasionally happens that the heart of a new-born infant may beat for a considerable time after its birth without any efforts at respiration. This is admitted in the communication from the Health Section of the League of Nations. Sometimes in such cases, even after the lapse of 20 or 30 minutes, the child begins to breathe and life is prolonged, and it is recognized as a live birth. The change in the definition of stillbirth proposed by the League of Nations to be perfect must therefore include also a change in the universally accepted definitions of "foetus" and "life." According to this proposal the evidence of life in the new-born would differ from the well recognized evidence of life in adults. Changes in definition are only permitted in science when discovered facts clearly necessitate such alterations.

Confusion—Law looks to science for guidance in such matters. It would be unfortunate for legal purposes if the fact of life could not be determined at the moment of birth, but had to be postponed until artificial respiration had been attempted and its results determined. The League definition seems to be based upon presumptions which have not been scientifically proved; namely, that heart-beat is not a sign of life, or that a child is not really born until it breathes.

If, because it does not breathe, a child is to be pronounced dead at birth although the heart beats for half an hour after birth, what shall be said of a similar child in which respiration is finally established? Was this latter child also born dead, and was it "raised from the dead"?

Foetus, or Foetal Character?—Before it is born the child is not an independent organism, because it depends entirely upon the maternal body for nutrition and the elimination of waste products. In this stage its lungs are collapsed, and most of its blood passes directly from the right to the left side of the heart through the foramen ovale, and it has no teeth. Normally the air cells of the lungs begin to be expanded immediately after the child is born, and circulation through the funis, by which it was formerly coördinated with the mother is stopped. Eight or 10 days after birth the foramen ovale becomes closed.

The change from "*foetus*" to "child" is immediate, at birth. This is a point of time clearly marked by nature. The change from the foetal condition to that of an individual is gradual. It normally takes 8 days after the birth in its grosser aspects, and years in the final changes. Abnormally any of these changes may be delayed.

Efforts at Breathing, or Expansion of Lungs?—For proper function as an individual it is necessary that enough of the air cells in the lungs

shall expand to satisfactorily aerate the child's blood. Often this does not occur. By the partial operation of the cells of the lungs life may be prolonged a short time, but the child may die 1 or 2 weeks after its birth from the atelectasis which has been present from time of birth, and from a cause operating before or during birth. It is not the fact of breathing, but *a full use of the lungs* which in that regard marks the transition from the foetal character to that of a child. A patent foramen ovale is a "foetal character," even when found in an adult. The very real distinction between *foetus* and *foetal-character* has apparently been entirely overlooked by the proponents of the League definition.

Inconsistent and Conflicting—The Health Section of the League of Nations asks that the organism be called a "foetus" until it breathes. Then by the League definitions it is to be called a "child," but the birth of that child must be recorded as of the time during which by the same definition it was a "foetus." These two requirements are inconsistent and conflicting, and if the expansion of the lungs is imperfect the proposed definition substitutes an imperfect datum for one which is exact. Is the child with marked atelectasis essentially any less foetal than before its feeble respiration began?

Science and Law—Although law looks to science for guidance when scientific points are involved, it may ignore illogical, uncertain and unproven statements. It is very important that the scientific and legal definitions shall be harmonious. It is the moral duty of this Association to promote this harmony. It would be unfortunate if the Association should place itself on record as supporting scientific ideas which the courts would not accept.

Scientific Conclusions—Science is a systematized and classified knowledge of facts. The proposed change in the definition of stillbirth does not appear to be based upon such an orderly classification of known facts. It seems to be based upon misty theory, contrary to established concepts. It is therefore unscientific.

III. LEGAL ASPECT

Vital Statistics Depend on Law—Statistics of birth, stillbirth and death are based upon records of these facts. These records are received in the form of legal certificates. These certificates are required by statutory enactment. The common use of the individual certificates is for legal purposes. Vital statistics, therefore, stands on a legal base and should be in harmony with the law of the land. Although the time for determination of fact of stillbirth or live birth may not be of preëminent importance either statistically or scientifically, the legal definition is sometimes very important. Such cases have consequently been ap-

pealed to the high courts, and there decided by old established rules. These common law decisions stand as law, except where modified by statutory enactment.

Evidence Acquired by Law?—Swinburne's Treatise on Wills,* first published in 1590, was the leading recognized authority for over two hundred years in England. Even to the present day it is the basis of Anglican legal decisions relative to live or dead births. In that book it is written: "Crying is not an only proof of life, since it may be proved by motion, breathing, and *such like*." It will be remembered that Judge Swinburne died before Harvey's work on the circulation of the blood was published, but the clause "such like" covers heart-beat.

With the knowledge of circulation of the blood, the English Courts have admitted heart-beat as evidence of live birth, and American decisions have followed those in England. Title to property and other legal rights may depend upon the decision whether or not a dead child was born alive. The legal registration should therefore be in accord with the legal definition.

Legal Interpretation—Every statute must be interpreted according to the facts known and recognized at the time the statute was enacted. Our present statutes in all the states were enacted when the legal determination of fact of live birth might be made upon the observation of heart function alone. The American Public Health Association has no power to change the laws of the several states. While it is well for leaders in various special lines to call attention to scientific advances, and to the need for statutory changes when such alterations are evident, the proposed change in the definition of stillbirth if adopted by the American Public Health Association could not be legally operative until embodied in statutory law by special enactment, and the necessity for such enactment is not evident. The conclusions of the committee were:

Because the change in definition of stillbirth proposed by the Health Section of the League of Nations so far as relates to evidence is not clearly needed for statistical purposes; and

Because it is not in accord with the recognized facts of science; and

Because it is neither in harmony with Common Law, nor present statutes,

Your committee recommends that the definition offered by the League be not accepted and that the present rules of statistical practice regarding this subject be reaffirmed.

The Relation of Public Health and Clinical Laboratories*

THOMAS G. HULL, PH.D., FELLOW A. P. H. A.

*Chief Bacteriologist, Illinois Department of Public Health,
Springfield, Ill.*

A SURVEY of laboratory work was recently made in the State of Illinois covering the calendar year 1926. Questionnaires were sent to 192 laboratories and 13 public health laboratories. Replies were received from 78, or 40 per cent, which was a good response for the first call without a follow-up reminder.

In Table I, is listed the amount of work actually reported and the estimated total if all laboratories had reported. This estimate is conservative because some of the largest laboratories, as well as the small ones, failed to make returns. The survey omitted the federal institutions, such as the U. S. Army at Ft. Sheridan, the U. S. Navy at Great Lakes, the U. S. Veterans Bureau at Maywood; state institutions such as the Psychopathic Institute, the State University, and the various state hospitals and penal institutions; county institutions such as county hospitals and sanatoriums. A large amount of the work performed by the above institutions is clinical in character although many public health problems are confronted. At any rate, these institutions cannot be considered competitors of private laboratories and hence can be omitted from this study.

TABLE I
LABORATORY EXAMINATIONS MADE BY CLINICAL AND PUBLIC HEALTH LABORATORIES IN
ILLINOIS IN 1926

	Examinations reported in survey	Total Estimated
Clinical Laboratories	619,793	1,735,888
Clinical work	513,301	1,301,200
Public health work	106,492	434,688
Public Health Laboratories	388,993	388,993
Total	1,008,786	2,124,781
Wassermann tests		
Clinical laboratories	45,803	139,829
Public Health Laboratories	88,203	88,203
	134,006	228,032

* Read before the Laboratory Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927

"Public health laboratory" work includes here the communicable diseases, milk, water, sewage and oyster examinations. "Clinical laboratory" work includes blood counts, urine examinations, blood chemistry, gastric contents and the like, which is of personal concern to the patient but not the public, whether done in private or hospital laboratories.

In 1926 there were 2,124,881 laboratory examinations estimated to have been done in Illinois by public health and private laboratories.

COMMENT

Recently a letter was circulated among clinical pathologists with the following statement: "The state laboratory has been one of the most important problems confronting the clinical pathologist and vitally affecting his economic status." The writer, who represents one of the national scientific societies, goes on to criticise "the gratuitous treatment of the mass of our population who would consider it an insult to receive coal and provisions free and yet take laboratory state aid as a matter of course."

It is only natural that there should be certain antagonisms at times between clinical and public health laboratories. They have grown up side by side in the last few decades.

Thus in Chicago Dr. W. A. Evans, with others, founded the Columbus Laboratories, in 1894, in an effort to teach physicians the new science of laboratory work so that the physicians could carry out the procedures in their own offices. The next year the Chicago Health Department founded its laboratory.

The figures presented in this survey do not indicate that public health laboratories are a great factor in competition with the private laboratories. After there has been deducted from the 18 per cent of total examinations performed by public health laboratories the specimens from the poor and from penal and charitable institutions, along with the specimens from private physicians which would not otherwise be examined, the work left would not greatly enrich the clinical pathologists.

One of the chief causes for complaint has been the Wassermann test. Although syphilis forms one of the most serious problems with which our health departments have to deal, no constructive program has been offered by those individuals who would like to do more Wassermans. They are at present making the majority of the tests and it is doubtful they would get a very much added increase if the public health laboratories ceased to do them.

This brings us to another factor. The development of laboratory work in a community is the result of agitation and stimulation. Thus there was a sharp increase in the number of sputum examinations following the campaign against tuberculosis beginning in the early nineteen hundreds. A similar increase in Wassermann tests began with the work of the Interdepartmental Social Hygiene Board in 1917. There are many communities now without laboratory service because the people and the physicians there have not been taught the value of laboratory aids. Public health laboratories can be of tremendous service in such instances in agitating and educating, thus enabling private laboratories to get a start or to do more and better work. This is a proper function of a health department in improving the health of the people.

CONCLUSION

It may be stated that the private laboratories have small cause for complaint against competition from the public health laboratories, since the latter make but a small percentage of laboratory examinations, many of which would not otherwise be made at all. On the other hand, the public health laboratories can be of service to the clinical laboratories in the promotion of laboratory work among physicians and populace in a manner that the private laboratories cannot undertake. The public health laboratories should coöperate to the fullest extent with the clinical laboratories, since the latter do more work of a public health nature than do the public health laboratories themselves.

Budapest Congress for Industrial Accidents and Occupational Diseases

THE United States will be represented by prominent sanitarians at the 5th International Medical Congress for Industrial Accidents and Occupational Diseases to be held at Budapest during September, 1928. Emery R. Hayhurst, M.D., is chairman of the National Committee of the United States which consists of Volney S. Cheney, M. D., Chicago, Ill.; R. W. Corwin, M.D., Pueblo, Colo.; Eugene L. Fisk, M.D., New York, N. Y.; Otto P. Geier, M.D., Cincinnati, O.; Leonard Greenburg, Ph.D., New Haven, Conn.; George M. Kober, M.D., Washington, D. C.; W. J. McConnell, M.D., Philadelphia, Pa.; Lloyd Noland, M.D., Birmingham, Ala.; Francis D. Patterson, Philadelphia, Pa.; George M. Price, M.D., New York, N. Y.; Frank L. Rector, M.D., Chicago, Ill.; Wm. A. Sawyer, M.D., Rochester, N. Y.; Henry F. Smyth, M.D., Philadelphia, Pa.; and C.-E. A. Winslow, Dr.P.H., New Haven, Conn.

American sanitarians, physicians and dentists are invited to contribute to the program. Those interested in making contributions are asked to communicate with Emery R. Hayhurst, M.D., Hamilton Hall, Ohio State University, Columbus, O.

Chicago's Tuberculin Testing Program*

HERMAN N. BUNDESEN, M.D., Sc.D., FELLOW A. P. H. A.

Former Commissioner of Health, Chicago, Ill.

AND

H. C. BECKER, M.D.V.

Department of Health, Chicago, Ill.

THE most important, as well as the most prevalent, disease of animals with which health officials have to deal is bovine tuberculosis.

Great strides have been made in the field of the sanitary production of milk and in safeguarding of market milk throughout the United States; yet it must be admitted that but slow progress has been made in eliminating tuberculosis from dairy herds. In the past two years, however, Chicago has advanced rapidly in the latter respect. It is the purpose of this article to review the methods and show the results obtained in her comprehensive campaign to protect the milk supply against bovine tuberculosis. For better understanding of the subject a brief review of the history of tuberculin testing in Illinois will be given.

The first legislative attempt to procure milk from non-tuberculous dairy herds for the City of Chicago was made in the year 1908, when a city ordinance was passed requiring the tuberculin test of cattle furnishing milk to be consumed in the raw state.

This step met with most strenuous opposition from dairymen and unscrupulous cattle dealers, arising principally in the most heavily infected dairy districts of Illinois. Through the efforts and influence of this group of interests a bill, known as the "Shurtleff Act," was passed by the Illinois State Legislature in 1911, which prohibited any city, town or village in the state of Illinois from enforcing the tuberculin test to safeguard the milk supply. This led to the passage of Chicago's first pasteurization ordinance in 1911.

Traffic in diseased cattle in northern Illinois had been engaged in for many years, and it developed still further under the influence of the Shurtleff law, coupled with the fact that neighboring states were requiring the tuberculin testing of cattle. Finally, in 1914, so many diseased cattle were being shipped out of Illinois into the other states

* Read before the American Public Health Association at a special session on Milk, at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

that the federal government placed a quarantine against five of the heaviest milk producing counties of the state. This quarantine prohibited the shipment of cattle either in or out of the five counties unless accompanied by a tuberculin test certificate, issued by a federal inspector.

In 1915, Illinois passed a law which prohibited the entrance of cattle into the state unless accompanied by a tuberculin test certificate. With the passage of this legislation the federal quarantine was released. It is common knowledge, however, that the passage of this law was not entirely effective in preventing the smuggling of diseased cattle into Illinois.

OCCASION FOR TEST

Sane and sound methods of eradicating bovine tuberculosis, which included indemnity for losses sustained by herd owners, have for several years been provided by the federal and state governments.

In certain localities of the Chicago district such aid was not accepted by the dairymen, who apparently expected to rely indefinitely upon pasteurization for making safe what was otherwise an unmarketable product.

Realizing that tuberculosis in herds was on the increase in the largest milk producing counties and that the situation was gradually becoming more acute, an investigation of bovine tuberculosis in relation to the milk supply was made by the State Department of Health.

During the years 1923, 1924 and 1925, Tonney, White and Danforth examined in the Bureau of Laboratories and Research, 329 samples of raw milk to determine the incidence of the tubercle bacillus in this product.

Of the total number of samples examined from all sources, 3.5 per cent were found to contain virulent bovine tubercle bacilli. Of the samples collected from one of the largest milk producing counties, 6.8 per cent proved to be positive.

Three and five-tenths per cent of the total milk supply of Chicago amounts to 43,750 quarts daily, or approximately 15,000,000 quarts a year, which, according to the experimental data, contained living tubercle bacilli.

Examination of the official records of the state and federal authorities showed that the percentage of infection among herds in the counties from which the major part of Chicago's supply was obtained ranged from 25 per cent to as high as 77 per cent. Incidentally, the degree of infection in most counties was proportionate to the amount of milk produced. This statement is not to be construed as meaning that the entire supply was obtained from highly infected herds. On the con-

trary much of it came from herds of more progressive dairymen, both in this territory and at more distant points in which the percentage of infection was very low.

The shortcomings of pasteurization as a sole means of protecting the consumer against bovine tuberculosis was also realized.

Sanitarians are almost unanimous in the opinion that pasteurization is not and never was intended to be a safe corrective for milk from unhealthy cattle, nor a justification for lax and insanitary methods of production of milk. To afford maximum protection to the consumer, milk must be obtained from healthy cattle, produced in a cleanly manner, and pasteurized as an additional safeguard.

With full knowledge of the facts and conditions, as here outlined, the matter was placed before the Advisory Board of the Department of Health, and many of America's outstanding authorities on the subject were also consulted.

That milk, even though pasteurized, should be obtained only from cows free from tuberculosis, and that pasteurization and tuberculin testing of dairy cattle should go forward together was, in substance, the opinion of these eminent scientists.

FUNDAMENTAL FACTS AND PRINCIPLES

Before the inauguration of Chicago's campaign, the following well established facts and principles were accepted after thorough consideration of all phases of the subject:

1. Bovine tuberculosis was prevalent to an alarming extent among the dairy herds supplying Chicago.
2. Living virulent tubercle bacilli were present in the raw milk supply.
3. Bovine tuberculosis is transmissible to the human family through the ingestion of milk containing the bacilli.
4. There occur annually in Chicago many cases of bone and glandular tuberculosis, known to be of the bovine type.
5. The efficacy of commercial pasteurization is dependent largely upon the human element and is not to be relied upon as the sole means of protection against bovine tuberculosis.
6. The economic losses caused by tuberculosis in cattle amount to a stupendous sum annually in the United States and the continued maintenance of diseased herds is economically unsound.
7. The federal and state coöperative plan of eradication is no longer in the experimental stage and has proved successful in eradicating the disease.
8. The foremost authorities of the country maintain that, even though milk may be pasteurized, it should always be obtained from cattle which are free from tuberculosis.

CAMPAIGN LAUNCHED

There seemed to be no rational excuse for permitting such a dangerous and uneconomic condition to continue at the risk of human life.

Accordingly, early in 1925 a campaign to secure milk from tuberculin tested cows was begun. With a view to producing as little disturbance in the industry as possible, the coöperation of the dairymen, city milk distributors and country bankers was conscientiously sought.

Numerous meetings, attended by the producers and their representatives, the city milk dealers and bankers, were held in the Department of Health. The producers pledged their support to the program with the proviso, however, that they be given from 5 to 10 years in which to clean up their herds.

INJUNCTION SERVED

Believing that such an agreement would result in unnecessary delay and perhaps postpone really effective action indefinitely, the Commissioner of Health declared that reasonably prompt action only would be entertained. A certain group of producers then resorted to legal action and, on November 24, 1925, secured in the Circuit Court of Kane County, Ill., an injunction against the Commissioner of Health and 12 milk distributors, restraining them from any further attempt to carry out the program. This effort to intimidate the Department of Health and, in effect, to dictate the kind of milk that Chicago should use, aroused strong sentiment on the part of the public and the press, with the result that, on December 24, 1925, the City Council passed an ordinance, providing that on and after April 1, 1926, all dairy herds supplying milk to the City of Chicago must be free from disease.

The same opposing forces which were responsible for the passage of the Shurtleff law in 1911, again became active. Mass meetings were held throughout the dairy district. Defense funds were raised and every conceivable attempt was made in an endeavor to defeat the enforcement of the new ordinance on April 1. Many contended that its enforcement would force most dairymen into bankruptcy. Others predicted that its enforcement would result in a milk famine in the City of Chicago, and that milk would be advanced in price to 50 cents a quart.

It should not be inferred that all dairymen were opposed to the program. The majority of the producers of the dairy district, as a whole, either were in favor of the movement or did not oppose it. The antis consisted of a relatively small group of misinformed dairymen, cattle dealers and bankers in a few of the badly infected counties. The noise and outcry of this group was out of proportion to its numerical strength. With the Health Department's refusal to relent and its repeated insistence that the ordinance would be strictly enforced on April 1, the distributors exerted active effort to enroll their patrons for the

test and much progress was thus made in a comparatively short time.

ORDINANCE ENFORCED

Beginning April 1, 1926, the ordinance was strictly enforced. It developed that more than an ample supply of milk from approved herds was received and, contrary to prediction, the price of milk to the consumer was not increased.

For the approval of herds, a system was installed whereby every dairyman shipping milk to Chicago is required to have on file in the Department of Health, a certificate issued by the state and federal authorities, as evidence that his herd is under supervision. Much credit is due the various officials in charge of the eradication work for making this possible.

The herd certificates, when submitted for file, are carefully examined and a check is made of the amount of milk produced against the number of cows accounted for on the certificates. The date of the test is also noted, and a record is made indicating when the retest is due. A special file is kept of each dealer, containing the certificates of his patrons. With few exceptions, all of the counties from which Chicago receives its milk and cream supply are either testing under the county area plan, or have county veterinarians who, under the direction of the federal and state officials, conduct the actual testing.

RETESTING HERDS

It was held by many opponents of the measure that, after the first testing, many of the clean cattle with which the herds were replenished would be lost on the first retest. As an evidence of the fallacy of this view, the percentage of infected cattle in the 10 leading dairy counties of the Chicago dairy district on the initial test and the percentage of those reacting on the first retest are presented:

	Initial Test	First Retest
Cattle tested	142,185	55,509
Cattle reacted	57,514	4,244
Per cent reacted	40.4	7.4

TESTED HERDS PROFITABLE

It was contended that many dairymen would have to go into bankruptcy on having their cattle tested, because of the fact that their herds were so highly infected. Testimony has since been given by many dairymen that they are now producing a larger amount of milk from a smaller number of cows than before they tested and disposed of their reactors, and that their veterinary expense and loss from mortality has been materially reduced.

At 13 large milk plants, located in the Chicago dairy district, statistics have been kept concerning the average daily production of milk per cow, both before and after the test. The figures cover herds comprising 30,000 cattle. For the 12-month period after the test the average daily production per cow is given as 23.2 lbs., as compared with 21.5 lbs. before the test, or an increase of 7.3 per cent. The increase given, covering the 30,000 cattle included in the survey, amounts to 18,360,000 lbs. per year, which, at the average price of \$2.50 per cwt. paid for milk, represents a profit of \$459,000.00.

PREMIUM PAID FOR HOGS

Attention is also called to the fact that a premium of 10 cents per cwt. is being paid by the packers for hogs coming from modified accredited counties; that is, counties in which the degree of infection among the cattle in the county is less than 0.5 per cent. This movement has been sponsored by the National Live Stock Exchange, which advanced the following information: The amount of \$342,972.00 was paid in premiums for hogs at Chicago and markets West during the year 1926, one single county in Iowa having received \$23,250.00. The first 8 months of 1927, \$341,691.00 was paid, or an amount almost equal to that paid out during the entire year of 1926.

STATE AND FEDERAL PLAN

In the year 1917 the state and federal coöperative plan of tuberculosis eradication was inaugurated. One has but to review the figures in the August, 1927, report of the Bureau Animal Industry, U. S. Department of Agriculture, in support of the belief that under this plan bovine tuberculosis can be eradicated.

According to this report there now are under supervision 1,887,589 herds comprising 18,091,229 cattle; accredited 137,898 herds comprising 1,877,021 cattle.

This report shows 361 modified accredited counties in the United States; that is, counties where the per cent of infection has been reduced to less than 0.5 per cent. According to latest information, however, this has been increased to 410 counties.

That the importance of this work is being recognized throughout the United States is indicated by the increase in financial support it has received, particularly in the past 2 years.

The federal appropriation for the year 1927 is approximately \$6,000,000.00, or an increase of \$2,500,000.00 over that made in the year 1925 when the Chicago campaign was inaugurated.

The combined states and federal appropriations for the year 1927

are given at \$18,500,000.00, or an increase of \$5,500,000.00 over the year 1925. This does not include appropriations made by counties for the employment of county veterinarians.

The following is quoted from the President's annual message for the year 1927, when transmitting the budget:

The furnishing of pure milk is of vital importance to the health of the people. Because of its interstate character, it is entirely proper that the federal government share with the states the cost of protecting this great food supply. The amount included in the estimates should permit adequate prosecution of the work of eliminating tuberculous cattle from dairy herds. The results of the work already done warrant the belief that we can confidently expect the complete elimination of this menace to health.

That the movement is receiving popular support is evidenced by information received from many cities which have since put into effect similar legislation. Practically all of the smaller cities surrounding Chicago are now requiring that milk come from tested herds.

While the progress thus far made is considerable, the cleaning up of the fluid market milk, though most important, is but one step in the program of elimination of bovine tuberculosis infection from dairy products. The task will not be completed until all such products are required to be obtained from cattle which are free from tuberculosis.

Larson Directs National Dairy Council

THE new director of the National Dairy Council is C. W. Larson, Ph.D., Chief, Bureau of Dairy Industry, U. S. Department of Agriculture since the Bureau was established in 1924. The appointment was made at the annual meeting of the Council in Chicago, Ill., on December 1.

M. D. Munn was reelected president. The other officers elected were: E. M. Bailey, President of American Dairy Federation, Pittsburgh, Pa.; and J. A. Walker, Blue Valley Creamery Co., Chicago Ill., Vice Presidents; T. A. Borman, Beatrice Creamery, Chicago, Ill., Treasurer. C. Bechtelheimer, secretary of Iowa Creamery Buttermakers Assn. was named secretary pro-tem.

The National Dairy Council, representing leaders of the dairy industry in all sections of the country, is devoted to educating the public concerning the benefits of milk and its products. In his presidential address, Mr. Munn said:

Production of milk has increased in the last six years 34.7 per cent. This had been made possible by assured demand, which also had made possible more efficient and sanitary methods of dairying. Nearly all of it has been consumed in this country. Per capita consumption of milk increased 28.6 per cent and butter 21.36 per cent from 1920 and 1926, inclusive.

The changing food habits of the American people have brought about the increase in milk consumption. With the population centered in cities, people are using green foods, fruit and dairy products, the protective foods much more prominently in the diet.

The dairy industry is in a favorable position both as to production and as to present demand, but according to dietary scientists the American people should be consuming 45 per cent more dairy products than they are using at the present time, in the interest of national health and from the standpoint of economy of the food budget.

Herman N. Bundesen, M.D., President of the A. P. H. A., was one of the speakers at the annual meeting of the National Dairy Council.

The Nation-Wide Campaign for the Early Diagnosis of Tuberculosis

PHILIP P. JACOBS, PH.D., FELLOW A. P. H. A.

*Publicity Director, National Tuberculosis Association,
New York, N. Y.*

TWENTY years of campaigning up and down the length and breadth of the United States in the face of a rapidly declining death rate! Why is it necessary at this time to organize a nation-wide campaign for specific emphasis on early diagnosis of tuberculosis, such as is being planned by the national, state and local tuberculosis associations during March, 1928? Has not tuberculosis decreased to such a point that specific emphasis on this disease is unnecessary? Why not a campaign for health examinations instead of this special emphasis on tuberculosis?

To answer these questions, a certain amount of historical perspective is necessary. When the National Tuberculosis Association began its campaign for hospital provision for the tuberculous, following the Sixth International Congress on Tuberculosis in 1908, two types of institutions were projected: state sanatoria for early and incipient cases of tuberculosis, and hospitals of a local, county, municipal or district character for advanced cases.

Newsholme contended at the International Congress that the hospitalization of the advanced foci of infection had contributed most to the decline of the tuberculosis death rate. His thesis had much to do with the establishment of local and district hospitals. As time went on, however, these local institutions, as well as the state institutions, although legally of a decidedly differing character, were both compelled to admit all classes of cases.

The reasons for this change in practice in the face of the accepted theories of 1908, 1909 and 1910 are clear.

At this time interest in tuberculosis was confined to a handful of specialists; the rank and file of the profession was not well versed in the diagnosis of tuberculosis. Consequently, little discrimination was exercised in sending incipient and far advanced cases to the respective institutions provided for them. This failure to hospitalize the early cases has influenced sanatorium construction, and the "shack" that 25 years ago was designed for early cases exclusively, is now relatively unknown. Even at the present time, as recent studies have shown, less than 20 per cent of patients admitted to tuberculosis sanatoria are in the early stages of the disease. It is obvious that tuberculosis is not, in most instances, being discovered early.

Another evidence of the fact may be seen in the failure of physicians to report tuberculosis to the proper health authorities. As Plunkett has recently pointed out, with very few exceptions the state and local health authorities of this country have on record less than two cases on an average for every annual death. Since Armstrong's studies at Framingham indicated that nine active cases should be reported for every annual death, the records of living active cases will seem to be woefully inadequate. The reason for this incomplete reporting is found in the inability or the unwillingness of physicians to report tuberculosis until it has practically arrived at a fatal termination.

Still another reason for an early diagnosis campaign may be found in the experience of the national, state and local tuberculosis associations for the last ten or twelve years. The emphasis upon the child as a vital consideration in the prevention of tuberculosis, which began about fifteen years ago and has steadily increased in stress, had the inevitable effect on the tuberculosis campaign of broadening its scope and outlook. With tuberculosis conceived of as a childhood infection, developing into actual disease in early adult or middle life due to stress and strain and faulty personal and community hygiene, the campaign to prevent this disease has naturally become a broad public health movement. Thus the activities of many of the local and state tuberculosis associations have been dissipated upon comparative non-essentials in the tubercu-

Figure 11.—“Let Your Doctor Decide” is the slogan for the Early Diagnosis Campaign. The diagnosis of tuberculosis demands a skillful examination of the patients with bared chest.

losis movement, such as nutrition classes, vacation camps, sometimes wrongly called health camps, dilettante methods of health teaching both for children and adults, etc.

A year ago a committee of the national, state and local tuberculosis associations met in New York and decided, after some discussion, upon a plan for an annual national campaign of a strictly educational character. Some fifteen different subjects for such campaigns were considered and after careful elimination of one after the other, the early diagnosis of tuberculosis was decided upon for 1928, largely for the reasons herein enumerated. In planning the campaign, the Advisory Committee on Publicity and Publications, which had the matter in charge, wisely conceived of an organization comparable in scope to the well-known Christmas Seal Sales of recent years.

This campaign planned well in advance, has been under preparation for many months. In order to insure a nation-wide effect, rather than a spotty, scattered series of local endeavors, the national association has planned to distribute free to its affiliated associations over \$25,000 worth of posters and other forms of printed matter and educational matter, to give each state a nucleus for an educational movement. Additional literature will then be purchased by the states in accordance with their ability and interest. Every state, however, will have a supply

of material with which to work and a generous allotment has been allowed.

Through the courtesy of the Outdoor Advertising Association of America, it is anticipated that billboard space will be made available, ten thousand 24-sheet posters will be provided for that purpose. The design of this 24-sheet poster has been executed by F. G. Cooper, the famous letter artist whose food and thrift posters created so much interest during the war and post-war years. A small poster, designed by Ernest Hamlin Baker and drawn from life, depicts a typical scene of a physician in his office examining a patient. Both in color and technic this poster is said by those who have seen it to be the finest of its kind that has ever been produced. This design will be used as a poster (size 11 x 22 inches and 11 x 14 inches), and also as a central panel in a three-panel window display and as a small posterette (size 2 x 2 $\frac{3}{4}$ inches).

Two motion pictures are being prepared for the campaign. The first entitled "Delay is Dangerous" is a one-reel film designed for lay audiences and illustrates the importance of early diagnosis from the patient's point of view. The four danger signs on which particular stress is laid are those depicted on the 24-sheet poster; namely, too easily tired; loss of weight; indigestion and cough that hangs on.

In passing it may be said that all of the medical aspects of the campaign have been carefully passed upon by a special selected committee

Figure III —Young children are endangered by prolonged contact with tuberculosis in the home. Between the ages of ten and fourteen, the tracheo-bronchial glands are often found infected. Discovery of this condition, known also as hilum or juvenile tuberculosis, is the first step in preventing the serious adult type of the disease.

of the Board of Directors of the National Tuberculosis Association. This is to insure scientific accuracy of statement.

The film for physicians entitled "The Doctor Decides" is in two reels and is particularly designed to impress upon the physicians the importance and necessity as well as some of the technic of early diagnosis. The National Tuberculosis Association plans to make both of these films available at practically the cost of printing, in order to give them the widest possible distribution.

The organization of the campaign is through the state and local tuberculosis associations. The American Medical Association will give prominence to the campaign by articles and editorials in its journals. Several of the leading life insurance companies will actively coöperate.

Talks before the public and before special groups of nurses, social and health workers, will be an important feature of the campaign. Newspaper publicity and other methods of getting over the mesesage of the campaign will be employed.

A manual of publicity and suggestions for the conduct of the campaign will be available about January 1. Copies of this manual will be furnished to any health officer desiring it either by the office of the National Tuberculosis Association or through the office of the state tuberculosis association.

The support of the health officers and of the American Public Health Association in general is naturally anticipated. At the recent meeting of the American Public Health Association in Cincinnati, the interest of the Association was expressed in the adoption of a Resolution to give its assistance in every possible way.*

Health officers and others who are willing to participate in this early diagnosis campaign are urgently requested to get in touch with their state and local tuberculosis and health associations. This campaign offers an excellent opportunity to stress the reporting of tuberculosis and also the need for increased individual and community action.

Any of the supplies to be used in the campaign, including the printed matter and motion pictures may be secured through the affiliated tuberculosis associations. It is hoped that in coöperation with the tuberculosis associations, the health officers will avail themselves liberally of these supplies and will utilize them in every way possible.

By united effort, with intensive publicity concentration in the month of March, 1928, the danger signs of tuberculosis can best be presented to the public.

* Resolution No. 6, adopted at the Fifty-sixth Annual Meeting of the American Public Health Association, October 17-21, 1927. *A. J. P. H.*, 17, 11.1163 (Nov.), 1927.

The Purification of Contaminated Oysters in Natural Waters

CHARLES KRUMWIEDE, M.D., AND WILLIAM H. PARK, M.D. FELLOWS A. P. H. A., AND GEORGIA COOPER, MARIE GRUND, CHARLES TYLER AND CAROLYN ROSENSTEIN

Bureau of Laboratories, Department of Health, New York, N. Y.

RESULTS of a reinvestigation of the cleansing effect of changing sea water on contaminated oysters was reported in the March, 1926, issue of the JOURNAL. Two experiments were made—one in a tank, the other in natural waters.

The tank experiment showed that there was a very marked reduction in the number of *B. typhosus* on or in contaminated oysters after 3 changes of sea water. However, *B. typhosus* in small numbers could still be isolated after 18 changes of sea water covering a period of 24 days. This experiment was not wholly satisfactory for several reasons: First, apparently due to insufficient aeration, the oysters started to die after the 15th day and the experiment was terminated by the lack of further viable oysters. Second, although the temperature maintained was satisfactory for drinking, the volume of changing water was in no way comparable to the volume of change which tidal flow would give under natural conditions with resulting wash effect and dilution. These considerations made it seem that the rate of cleansing in tanks must be materially slower than in natural waters. We, therefore, looked for a place where contaminated oysters might be returned to their natural waters without creating a menace. The water was too cold at this time (December and January) to insure active drinking, but it seemed desirable while waiting for appropriate temperatures to determine the viability of *B. typhosus* on or in hibernating oysters.

Oysters, native to the waters to be used, were accordingly contaminated by drinking them in sea water to which feces containing *B. typhosus* had been added. The contamination was light. The oysters were returned to their waters. After 24 hours *B. typhosus* could not be isolated from the shells. The liquors became negative between the 10th and 17th days. Enrichments of the pooled gills were still positive on the 51st day, when the supply of oysters was exhausted. With the onset of warmer weather we repeated the above previously reported experiment.

Two lots of freshly dredged oysters were obtained. One lot came from the waters where the experiment was to be carried out, and the other from relatively distant waters. This inclusion was thought wise in view of the privilege given dealers to transfer oysters from doubtful sources to clean waters during the closed season. Each of these lots was divided into two batches and one batch of each lot was lightly contaminated and the other more heavily. They were then returned to the natural waters for test. The details of these experiments are given in the tabular summary. In addition to the actual temperatures of the water taken at the time of obtaining the samples the Weather Bureau report is also given as a further indication of the water temperature in the intervals.

TABLE I
MEAN TEMPERATURE FAHRENHEIT
MAY, 1926

8	9	10	11	12	13	14
62°	53°	56°	52°	58°	59°	62°
15	16	17	18	19	20	21
64°	53°	65°	71°	66°	60°	58°
22	23	24	25	26	27	28
58°	55°	52°	60°	60°	58°	56°
29	30	31				
60°	63°	60°				

JUNE, 1926

1	2	3	4	5	6	7	8	9	10
60°	78°	63°	62°	59°	63°	64°	72°	75°	76°

It will be seen from these temperatures that the conditions were such as to insure active drinking. This, with the dilution and wash of the tides, results in relatively quick cleansing as compared with the tank experiment or with the experiment in natural waters, at hibernating temperatures.

Reference to the tabular summary shows that the foreign oysters became negative bacteriologically between the 9th and 16th day, the native oysters between the 11th and 24th days. It should be noted that the last positive result was with oysters contaminated more heavily than would be likely under ordinary modes of pollution of oyster beds. The waters in which these experiments were carried out were near condemned oyster beds. A relatively large sewage content enters nearby waters, yet the area of water used yielded only 6 *B. coli*-like types per c.c. of which 4 were *B. aerogenes* and 2 were *B. coli*.

To complete the data in relation to this experiment it seemed desirable to retest the viability of *B. typhosus* in sea water utilizing the same methods of cultural enrichment. Six c.c. of a fecal suspension of feces containing *B. typhosus* was accordingly added to 3.25 liters of sea water. This was kept in the dark at a temperature of between 15° to 20° C.

¹ Five oysters examined to 11th day, ten oysters from 16th day and later.² Quantitative estimates based on amount of fluid used to scrub shells, and total volume of body emulsified in broth.

NOTE—The gills were pooled in fives and incubated in brilliant green broth from the 11th day on. No positive results were obtained.

It will be noted that the mere addition of *B. typhosus* to sea water resulted in the death of nearly half the number. Although survival up to the 19th day was observed, this must be considered a practically maximum figure as the contamination was large and greater than occurs in the pollution of tidal waters.

In this connection it might be noted that in our previously reported experiment on the effect of changing sea water on oysters in a tank, we were able to isolate *B. typhosus* from the 16th change of sea water (21 days), but not from the 18th (24 days). These bacilli came largely from the sediment on the shells or bottom of the tank, possibly to a

Remainder of sea water (approximately 2 liters) enriched, no *B. typhosus* isolated.

slighter extent from the inside of the oyster during drinking. These bacilli were probably in contact with sea water the major part of the time and the period of viability checks with the results of the experiment given above.

DISCUSSION

Within the limits of our bacteriological methods, we may summarize as follows:

B. typhosus may survive in oysters for at least from 9 to 11 days, but were not found in examinations made on the 16th and 24th days. This applies to oysters in their natural waters when the temperature is high enough to insure active drinking. *B. typhosus* may survive in sea water between 19 and 24 days. For purposes of discussion we might take the approximate means of these figures, 2 weeks for the oysters and 3 weeks for the sea water. How should these figures be interpreted in relation to determining the minimum time that should be required for oysters to remain in clean waters when transported from doubtful sources? Likewise, should such oysters have been contaminated with *B. typhosus*, what bearing has this on oysters in the beds to which they are transported?

The Health Department of New York City allows such transport during the closed season but no dredging of beds to which doubtful oysters are transported is allowed for 30 days thereafter. Is this a safe limit in terms of our experimental findings? Is a vicious cycle of events a tenable hypothesis?—contaminated oysters discharge *B. typhosus* into the sea water until about the 14th day, some remain viable for about 3 weeks and are able to recontaminate oysters where a number of the survivors may persist for 2 weeks, etc.

Obviously such an hypothesis of continuance of infectiousness ignores the following facts: The experimental oysters were initially more heavily contaminated than is likely to occur in tidal waters, the enormous dilution effect resulting from the tidal flow reducing to a minimum the possible quantitative recontamination, the rapid numerical decrease of *B. typhosus* through death and the lessened viability of the survivors due to lack of foodstuffs and the continued unfavorable action of the salt water.

The last *B. typhosus* were isolated from the liquor or bodies of the oysters where it might be presumed that they were protected to some degree by mucus from the full effect of the salinity of the water. All the facts available seem to indicate that the total length of time of contact with sea water was the determining factor and that contaminated oysters transferred to new water would require for purification a period

of time equivalent to the time of possible survival of *B. typhosus* in sea water or at least not appreciably more.

This further evidence of the possibility of the survival of a minimal number of *B. typhosus* in contaminated oysters even where drinking is presumably at its potential maximum deserves a comment in relation to the "drinking" of oysters in tanks of chlorinated water. The evidence again emphasizes the conclusion that however desirable, such a procedure may be from the standpoint of relative reduction of contamination should it unknowingly exist or of obtaining a safe water for conditioning or for wet storage; the relatively short drinking period cannot be considered a purification process in that it will surely render contaminated oysters safe for human consumption.

CONCLUSIONS

On the basis of the experimental data obtained it may be concluded that oysters contaminated with *B. typhosus*, when actively drinking in their natural habitat become non-infectious in 3 weeks. *B. typhosus* in sea water die in about the same period of time. An ordinance allowing the transfer of oysters from doubtful waters to clean waters during the closed season with the proviso that no dredging in the latter waters be allowed for a period of 4 weeks after the transfer, covers observed facts and gives a reasonably generous excess margin of safety.

Embree President of Rosenwald Fund

EDWIN ROGERS EMBREE, former vice-president of the Rockefeller Foundation, on January 1, 1928, became president of the Julius Rosenwald Fund and associate of Julius Rosenwald in his personal philanthropies, with headquarters in Chicago.

Mr. Embree, following a number of years as alumni secretary of Yale University, has been with the Rockefeller Foundation since 1917, serving successively as secretary, director of the Division of Studies and during the past year as vice-president. In addition to general administrative work he has been responsible for activities of the Foundation in hospital and dispensary service, nursing education, mental hygiene, and the development of the biological sciences. He has spent much time abroad in surveys and studies for the Foundation, visiting most of the nations of Europe, as well as Latin America and the countries of the Pacific, including the Orient, the Pacific Islands and Australasia.

The Julius Rosenwald Fund is the only large Foundation general in scope outside New York City. Its character, like that of the Rockefeller Foundation, limits its work only to "the well-being of mankind throughout the world." Mr. Rosenwald's giving has covered a wide field of interest in relief, education, health and welfare.

Present Status of School Hygiene in the United States^{*}

JAMES FREDERICK ROGERS, M.D., DR.P.H.

*Chief, Division of Physical Education and School Hygiene,
U. S. Bureau of Education, Washington, D. C.*

THE YEAR 1927 has been one of stock-taking on the part of public health organizations, perhaps because it is the tenth year since the war. The war caused considerable agitation about health, and we find it easy to count by tens. Inventories are highly important for successful business, but good business methods are sadly lacking in much of our health work.

A general review of school health work as carried on in our forty-eight states is not an easy task. The result must be more or less impressionistic and this sketch does not pretend to be more.

STATE SUPERVISION

According to the formula of Herbert Spencer, evolution proceeds from the indefinite and incoherent to the definite and coherent. Taking the country as a whole we are still in a primitive condition as regards state-wide organization and administration of school health work. While there is advanced development in some quarters, there is, on the whole, considerable chaos. Where anything definite appears through the gloom, there are at least two visible shapes: The management of communicable diseases, delegated always to the state department of health, and physical education, whatever that may include, presided over almost exclusively by the state department of education.

When it comes to medical inspection and sanitation there is no such certainty as to what state authority should be in charge or whether anyone is in charge. This is due in large part to the changes which have come about as to the object of such work.

Medical Inspection—Medical inspection in our country began in a search for communicable disease. With the shift of emphasis, about 15 years ago, to the examination for defects, it became obvious that it

^{*} Read before the Child Hygiene Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

would be better to move the local administration of such work over to the educational authorities, save in handling communicable diseases; and this has been largely done. The states have moved more slowly, and only 7 have placed the management of medical inspection under the state department of education, although in 26 states the medical inspection law must be administered locally by the boards of education. In 9 states the medical inspection law is to be administered by the state health authorities, in 11 it is administered jointly, and in the remaining states no authority is specified.

Forty-two states have some kind of a school medical inspection enactment. In only 16 states is the medical inspection law or regulation mandatory for the examination of pupils in all school districts; in 11 states it is permissive for all districts; in 7 there is no law; while in other states there shall or may be examination of teachers only, or for dental defects in pupils.

As regards the extent of the examination, 19 states command or imply a complete examination, 10 do not specify the extent of the examination, while in the others the teeth, or the sight and hearing, or the sight, hearing and teeth, or some other combination of functions or organs, are to be looked into. One is curious to know just what wisdom directed the varying choice in this matter. As to who shall examine, 23 states specify that they are to be persons of special training: physicians, nurses, physical directors, or dentists, or some combination of these, while 13 states include the teacher among the examiners.

Sanitation—As regards sanitation of schools, which is related to communicable diseases and has been especially so considered in times past when fumigation was in practice, it is to be expected that this work would be placed by enactment under the department of health, and so we find it in at least 12 states. In 6 it is under the supervision of the state department of education. In 12 there is joint responsibility, and according to replies to our inquiries there are a few states in which there is no one in charge. In at least 1 state there is a special school sanitation law, but the enforcement of this law is not delegated to anyone.

In practice, the sanitary condition of schools is usually taken care of locally, if at all, there being no one in either the state department of education or of health who takes it upon himself, or is particularly interested in studying the subject and endeavoring to keep school buildings and premises sanitary, and educational in these directions. There are exceptions, however: the state department of health of Connecticut recently completed a survey of water supplies. The department of health of Indiana made 92 sanitary surveys of schools last year, ordered

improvements in 68 cases, and prohibited the use of 24 buildings until sanitary conditions were remedied. The department of health of Kentucky has been making a survey in 40 counties. Possibly such surveys are made in other states, but we have not had the time to make a study of this subject in connection with this paper.

STATE AND LOCAL ORGANIZATIONS

There has been, we believe, no recent study of sanitary regulations, but at last accounts 12 states had no laws or regulations as to the provision of fire escapes or other means of fire protection for school buildings. More than half the states have regulations with regard to the provision of drinking fountains, but such fountains are often far from sanitary, while the water they supply may be from unsafe sources.

More than a fourth of the states had no legal provision for the supply of a privy, and in these states there are not only many schools without such a convenience, but, unfortunately, this occurs in some states which can least afford to be careless of human excreta. As an example of the turning over of a new leaf in the book of school sanitation, the revolution as to supply of toilets and their proper construction in North Carolina is most encouraging. A recent letter from the Director of Sanitary Engineering of North Carolina states that the installation of sanitary privies has been accomplished in all municipalities and villages. Unfortunately the law thus carried into effect is not state-wide as to rural schools.

The consolidation of schools has brought with it improvement in all sanitary arrangements and especially in sewage disposal. About one-third of the children from rural and village homes are, however, still in one-room schools. Consolidated schools are not without their drawbacks, and the question of heating and ventilation becomes of especial importance.

Half the states have specific laws regarding the ventilation of school buildings, and these laws seem to reflect an earnestness in the cause of health which is most creditable, for they entail much monetary outlay. Unfortunately they would now seem to have been of too specific a nature; but the legislator, who is presumably a practical man, has cause to question the fickleness of science, and he will want very good reason before revoking these ventilation laws.

The establishment of open air schools was an admission that ordinary classrooms are unhygienic. The reduction in the number of overheated rooms is a move toward better hygiene, but we ought to leave no question as to healthfulness.

There is general appreciation of and improvement in the lighting of

schoolrooms, and also in seats and seating, though we have far to go in some sections, for artificially lighted and poorly lighted schools are still to be found without much searching in our cities. No type of seat or desk really fits any child for very many minutes, but the fit ought to be better in a larger proportion of schools than it is.

If state-wide school sanitation is rarely satisfactory, neither is it so in some large cities with all their machinery for its promotion. In the sanitary survey of Philadelphia for 1924-25, 26 schools were classed as "poor," and ten as "bad," though this city is no exception. Nevertheless improvement is going on everywhere.

Physical Education and Health Teaching—Thirty-five states now have laws requiring physical education (which usually includes the teaching of hygiene). Although this is a prominent landmark amidst the confusion of administrative practices or allotment, even here there is in 5 states specification of participation by the department of health in control. In 10 states no organization is responsible for promotion of the school health educational program, and in 8 this great responsibility is shouldered on the department of health which is outside the school field and, besides, more than has its hands full with other activities.

ORGANIZATION IN STATE DEPARTMENTS

It is encouraging to find 15 states showing sufficient interest in the subject of school health (aside from medical inspection) to make someone responsible for getting this work under way and keeping it going. Fortunately, these states comprise half the school population of the country so that the general picture is better than mere numbers of states would suggest. There is, however, little evidence in most quarters that the promotion of health is considered in practice, with nearly the concern with which it is regarded in theory. In fact, in at least 3 states, although the law establishes the position of state director of health and physical education, no funds are appropriated to fill the position.

From this necessarily blurred picture of the general conditions as to state organization and regulation of school health work one must expect much dissatisfaction among state officials, and this is almost universal.

In a few instances, very good work is being done under the direction of state departments of education, departments of health, or with joint supervision. It all depends on personnel, coöperation, and available funds, although it would seem that the personnel for this work could be most advantageously installed in the office of the department of education.

That state supervision of medical inspection produces quantitative

results is evident if we can trust statistics: Pennsylvania claims the examination of 98 per cent of pupils enrolled; New Hampshire "practically all"; Virginia 91 per cent; New York about 80 per cent. Possibly some other states do as well, but we have no records and for most of them the number examined in rural schools must be very few indeed.

LOCAL SCHOOL HEALTH WORK

With the diversity in laws and of active interest and positive stimulation and guidance of health work existing in state departments, we may expect to find all degrees of excellence of work carried on locally, and much mediocrity or even absence of work. Since this latter condition of affairs exists in some localities where there are excellent state laws, state supervisors, and a genuine interest in health promotion, we can expect very little progress where there is nothing of the sort.

So far as the finding of defects is concerned, medical examiners have, since the time of Cohn, been most interested in the matter of vision; yet from an estimate of the Joint Committee on Health Problems in Education not half of the school children of the United States have ever had their eyes examined. This signifies that in not more than half the schoolrooms of the country has any attempt at medical inspection been made, and yet we are still talking of how very much shocked we were over "the revelations of the draft."

Information received by the Bureau of Education is fairly definite regarding larger cities, but becomes hazy as we approach the smaller cities, partly from lack of replies to inquiries and partly from indefiniteness of the answers. Judging in a general way from these returns, in most states there is practically no medical inspection worth the name in communities having a population of less than 10,000. There are plenty of exceptions in some states, but this can be considered the rule. The forces interested in health work are weak in smaller communities and the boards of education move along conventional lines. Even in cities of between 10,000 and 30,000 population, only about two-thirds report the employment of a school physician.

A large proportion of school physicians are on part-time, which may be advisable for assistants, but not usually for the physician in charge. Their pay ranges from \$.42 to \$4.00 an hour, and it is safe to say that in most cases the school gets no better service than it pays for.

A nurse is employed by practically all cities of over 30,000 population and there is an average of 2 nurses to 1 medical school officer and about 1 nurse per 3,000 children. Three-fourths of the cities from 10,000 to 30,000 employ nurses, and these average the same number as physicians.

An annual examination of pupils is attempted by about 50 or 60 per cent of these cities, the examinations being made to an increasing extent, in part, at least, by teachers and nurses and in most instances there is a physician to check up the findings of other examiners.

In communities under 10,000, and particularly those under 2,500 population, there is a decided falling off in physical examinations, and, except for certain states which stand out as exceptions, there is very little of such practice in villages and in rural schools; in other words, for half the school population of the country. In the notable exceptions, there is a mandatory law, for the carrying out of which a state department is made responsible.

Health work in rural schools, along all lines, halts because of lack of adequate district or county organization for both education and public health and lack of close coöperation between such organizations.

QUALITY OF MEDICAL INSPECTION AND RESULTS

Medical inspectors have been engaged too much in the tedious business of finding any or all defects regardless of whether these really needed correction or were even correctable. It is needless to say that few medical inspectors have had any special training for their work, and the lack of research by American workers in this field is appalling. The remark of Dr. James Kerr that "medical inspection of school children ought to have added enormously to our knowledge, if it had been scientifically organized," is doubly true in our own country. But it is largely a matter of recompense. The physician who determines vision only by the Snellen card, uses the same tongue depressor on all children, and reports all large tonsils as defects, is what we may expect to get for our money.

An improvement is slowly coming about, in that information about children is being secured from those who know them most intimately and in a working capacity. Parents and teachers are given grudgingly to some extent the place they deserve in the scheme of child study. The teacher is expected to show an interest if Johnny Jones cuts his finger, but it is more essential that she, above all persons, observe whether the said Johnny can see his letters, or hear her voice. The parents must some time learn about defects, and why not first-hand when they can be helpful in determining whether a defect is really worth correcting? We are more likely to get defects corrected if we present the need directly instead of beating about the bush with notes from principals or with expensive visitations from the school nurse. There are practically no school physicians or nurses for half the school children of the country; but there are teachers for all of these, who, with comparatively little

training, make as good examinations as the average school medical inspector, and they are in a more strategic position for doing so. In either case the final diagnosis is made by the family physician or dentist. The hope for physical examinations for half of our children and for better examinations of the other half lies in a right training of these teachers. I speak from experience in the training both of medical students and of teachers.

Removal of Defects—We have not, on the whole, passed out of the stage of the mere finding of defects, for according to a report from one school district employing a physician, 60 per cent of the children were found defective, and but 2 per cent were treated, while in another district of the same state 85 per cent were reported defective and 80 per cent corrected.

As examples of average results, we have the state-wide figures from New York (1923–24) showing 62 per cent defective and 44 per cent corrected. In Pennsylvania 1924–25 the figures are much the same.

Such statistics are often misleading, as the percentage of corrections is determined in part by the nature of the defects included, and the mere treatment may not mean adequate treatment. This all proves the need for better personnel and a knowledge of the essentials in defects and in their correction.

Taking the results at their face value, it is interesting to note that, although the number of defects reported in the city and rural schools is practically the same (1,000 per 1,000 children) the percentage of defects "corrected" in rural schools is just about half that in city schools.

Granted that the defects can be corrected and are worth correcting (and they should not be reported unless they are) it is a waste of time and money if after finding them they are not treated.

A review of the reports of the Division of Medical Inspection in Philadelphia for the past 10 years shows a remarkable uniformity in the proportion of physical defects corrected, which runs about 46 per cent for the more important defects or 55 per cent for all. In contrast, it is illuminating, however, to read that "remarkable results were secured at the Philadelphia Normal School where 96.3 per cent (double that for elementary schools) of all physical defects recommended for treatment were corrected," and the only persuasive factor not existing in the elementary schools is a regulation that all defects must be corrected "if the student is to continue as a teacher-training candidate."

Practically 100 per cent corrections are also secured in Connecticut by a similar edict of the state department of education as regards students entering its teacher-training schools.

We are always working from the top and perhaps in the course of a

half century we will make it a regulation that the child whom we compel to undergo the process of education shall be put and kept in condition to profit by that process.

However, where health is not considered an incidental matter by principal and teachers, really thorough work can be done and is done, and we have reports from a few school districts of corrections which reach near 100 per cent and, for some defects attain it. In 9 schools of one rural district all of the 1700 pupils had their dental defects corrected, and in at least one junior high school the principal has dared to lay down the law that no pupil shall be graduated who has not had his teeth placed in 100 per cent repair. If such a ruling could be extended to cover all defects, medical inspection would be placed on something better than a dilettante and sentimental foundation; there would arise a serious interest in the subject of what constitutes a remediable defect; and there would be a scurrying about to find medical examiners worthy of their tasks.

Dental Work—As regards dental defects which figure so largely in the general total, the medical examiner has been reporting only about 40 per cent of elementary children as having such defects when actually 90 to 95 per cent have an average of 7 carious teeth. One reason for poor results in treatment of these defects has been that the medical inspector has found only advanced conditions chiefly in temporary teeth, the majority of which could not be really corrected if worth correcting.

With the possibilities in prophylaxis developed through the work of the Forsyth Dental Infirmary it would seem that the chapter of dental work which dealt chiefly with rotting teeth can be closed, though it may take some time to open the new one in which these infinitely the most common of defects will be adequately dealt with. No matter however whether we anticipate, or wait for, decay dental defects should be dealt with at the earliest possible moment, and the examination for such conditions should be made by the dentist, dental hygienist or someone who knows the signs of beginning decay. We believe it is only a matter of time when the dental hygienist will be trained to do early fillings, the dentist being reserved for the more difficult and elaborate activities of his profession. In that advanced country, New Zealand, the routine work of the school dentist is done by such an assistant, and it would seem that most of such work could safely and economically be placed in her hands. Even by the older methods, where there is real interest in the matter, 100 per cent of corrections have been secured in some of our schools, and abroad, a thorough program has been carried out in at least one city at a surprisingly low cost and with the result that 90 per cent of the children now leave school with sound teeth.

Nutrition Work—Weighing and measuring of children has recently been a feature of school work hinging on the one side with medical inspection, and on the other leading to the interesting of pupils in habits conducive to health. Unfortunately it has been dragged too much into the strong current of standardizing which has swept the country and the use of tape and scales has been too exclusively associated with classification according to deviation below or above certain arbitrary standards. This, in turn, has given emphasis to quantity rather than quality in nutrition. The mere fact that a child does not weigh a certain number of pounds (even the lack of one pound may label him underweight) does not at all signify that he is not so well fed as a child who does weigh that number of pounds. Nutrition classes based on relative weights still exist, though we are of the opinion that their number is diminishing; but there is, fortunately, an effort to have all children better cared for at home. The noon lunch too, whether in city or rural schools, is vastly improved in materials and methods of service all over the country.

On the side of medical work, the tape and scales have been used as means of sorting children for special preventive measures against tuberculosis; those falling into a certain percentile group being considered "threatened" with this disease, to use a very convenient phrase. The studies of Morse, McDougal, Reisman, and others have quite upset this theory, and Hill has furnished ample proof that relative weight has nothing to do with the incidence of any of the common infections of childhood.

HEALTH EDUCATION

We have had 10 years of the new hygiene or "health education" as it is called.

In 15 states there is a state director of physical education in charge, and in at least 2 of these a specially designated supervisor of health teaching. In these states such work goes much better than in others, though the existence of a state official cannot make up for lack of teacher-training or of local supervision and direction.

Local Supervision—From the beginning of this work the teachers were not prepared by their training, and what they are not specifically prepared for they seldom do without direct supervision. Even with the large turn-over in teachers, the percentage so prepared must still be small in most sections of the country. It is probably safe to say that in three-fourths of the cities of all sizes health education of the new order is conducted to some extent in elementary schools. A special directing health teacher is employed in about 10 per cent of cities over 30,000 and in 5 per cent of smaller cities.

In rural schools with an enrollment of 10,000,000 children we find little or no such teaching, with many contrasting spots, however, where there is excellent district or county supervision by a special hygienist or thoroughly prepared teacher. In some of the western states where county superintendents are awake to the importance of health, there is even a demand for well prepared health supervisors which cannot be adequately filled.

It all depends on the local education authorities and we cannot expect these to be made over in a day, or to be more than local demand calls for and pays for. Many of these, when the matter of health work is inquired into, are likely to state that they have no funds, or no special teachers, neither of which are needed for doing excellent work along these lines.

The time devoted to teaching of health in elementary schools varies from zero up to 160 minutes per week, with an average of about 60 minutes.

Content and Methods in Health Teaching—Besides our failure to recognize the predominant rôle of the home and of parents in the scheme of health teaching, our efforts have suffered again from the current tendency to try to standardize the human being. This has resulted in setting down exact measures as to the amount of milk or water every child shall drink, how many hours he shall sleep, the number of his bowel movements per day and other rules equally absurd. Our teaching has also been upset by the weather-cockishness of science which in one season says the use of the tooth brush preserves the teeth, and in another says it does nothing of the sort; which makes much one year of calories and in another sees our salvation in vitamins; which talks one season of poisonous air, and in the next says that only over-heated air is injurious.

HEALTH TEACHING IN HIGH SCHOOLS AND COLLEGES

High schools, struggling under the load of college requirements, find scant time for anything of so intimately human importance as hygiene, and recent information received by the Bureau of Education shows that in not more than 25 per cent is any definite time set apart for class work in this subject, and we are not at all certain that even in these schools it is taught to all pupils. One school admits that this subject is taught only to girls. When taught, the time devoted to the subject varies from 15 to 225 minutes a week.

Nor do the colleges take the matter of health as seriously as we would expect. One of the oldest and most influential offers a course of only 3 lectures in hygiene as a preparation for the "art of keeping alive

and well," although 50 years ago 24 lectures were given to all students.

There is always the danger of running to the other extreme by over-doing such teaching and making the pupil tired of hearing about health and sick of trying to practice the laws of health. The subject is indeed a difficult one to handle wisely, and in our professional ardor we need to avoid its over-doing.

PHYSICAL EDUCATION

Taking physical education in the Spencerian sense, it includes all school health work, and in the special realm of the direction of physical activities of playground and gymnasium it attempts to minister to one of the primal needs of the child which makes for physical and mental health.

The director of physical activities is among the best paid of our specialists, a fact which speaks much for the recognition of this work. It found its way into the curriculum under the form of classroom gymnastic exercises intended as a means of counteracting the recognized unhealthful conditions of school existence. The 15 to 30 minutes a day (or the two periods a week) usually devoted to such work is absurdly small, unless it be considered only as a time of instruction in activities to be practiced elsewhere.

So long as past conceptions of education hold sway, it is not likely that further time for physical activities will be allowed in school hours, but opportunity for the practice of these should be furnished elsewhere.

Schools, particularly high schools, have been going to extravagant expense for coaches, paraphernalia, etc., for the few who participate in inter-school sports, and it is but logical that they should do as much for the rank and file. Adequate space and adequate supervision for the physical activities of all children for at least 2 hours every day of the week would seem to be a minimum need in every community. Very few can boast of this offering.

CONDITIONS TO BE MET

It is easy for us to sit in our offices and arrange school health programs and say they should go thus and so. But our plans often meet with difficulties in the mental attitudes of educators, school boards and communities at large, hanging over from medieval if not from primeval times. However, very few discouraging or discouraged remarks come from communities over 2500 population, and even in rural communities there is an appreciation of the importance of the health program reported by many superintendents.

No review of school health work is complete without consideration of the coöperation of the home, for, while other school matters may be

handled without help from parents, it is quite otherwise with the physical improvement of the child. We have overlooked this fact altogether in the past, but we are rapidly making amends. In the meanwhile the Parent Teacher Association has become our most helpful ally. I do not need to emphasize its importance.

Promotion and supervision of school health work by voluntary agencies, such as the tuberculosis association or Red Cross, exists statewide or locally in some sections of the country. While this seems a primitive condition, when we consider the theoretical interest in health exhibited by the educational world, it is better than no work, and leads in time, if wisely conducted, to the development of such work under the appropriate agencies.

The organizations especially interested in the hard-of-hearing, in the crippled child, and in the child with poor vision, have done excellent work in promoting special facilities for their education in city and to some extent in rural communities. Such work is progressing favorably.

The American Child Health Association remains a powerful agent in the stimulation of all forms of school health work, and we are all interested in the attempt at evaluating the actual value of our present practices which it has undertaken.

Among the very hopeful signs of the times is the great progress made in school health work along all lines in parochial schools. This activity is being stimulated and directed through the Bureau of the National Catholic Welfare Conference, and health education courses for teachers have already been introduced in some of the Catholic universities.

PRESCHOOL EXAMINATIONS

Among the recent developments we must mention the attempts made by various agencies to secure the physical examination and treatment of children prior to entrance to school. This is a laudable undertaking, but does not replace school medical inspection. The preschool child cannot be satisfactorily examined as to certain defects, and, besides, after entrance to school he retains many of those he had, and often adds new ones. Although children are examined every year in Philadelphia and 50 per cent of defects are reported as "corrected," the total number of defects reported in 1925 were: for elementary, 1050 per 1000 pupils; for junior high and trade schools, 837; for senior high schools, 800; and for normal schools, 1063. Seemingly at graduation from high school the student, although examined every year, with about 50 per cent of his defects corrected, has as many defects as in the beginning of his school career. If we omit dental defects, substitute the word "treated" for corrected, and remember that communicable dis-

eases, like the poor, we have with us always, these figures are not so discouraging as they seem.

SUMMARY

Considering the inertia of pedagogical tradition and the heavy weight of family custom and personal prejudice which must be overcome, we are really making rapid progress along all lines of school health work, and the few mistakes, due chiefly to the shifting sands of science and our current obsession for standardizing, have not thrown us much out of our course or caused us much regret.

There are a few points which seem to stand out as especially obstructive to progress. Our legislators have been quite generous toward school health work, but many of our laws would be more helpful if less specific as to details and more definite as to enforcement. There is need of integration, organization and competent direction of all school health work in state departments and locally. There is need of closer understanding and coöperation between health and educational authorities.

Medical inspection needs to be placed on a more businesslike basis, both as to examinations and treatments. Dental inspection should be completely divorced from other work and conducted by dentists or dental hygienists. Adequate teacher-training in health examinations and health teaching are of great importance and are not as yet fully met. There is need for the development of ample facilities for, and direction of, physical activities out of school hours. We have much to learn in regard to school sanitation, and there is still the troublesome problem of communicable diseases and of malnutrition, which together are prominent factors in practically all of the defects and diseases of school children. Immunization against communicable diseases must be carried out as far as possible. The home must be hitched up with the school in interest and knowledge of child health if we are to get very far.

After all, however, the child arrives at school at a comparatively advanced stage of development and already possessed of most of the physical defects he will have during all his school days. The school cannot undo what has been done. We need to begin much earlier than the school period to advance the physical and mental welfare of the race, but by whole-hearted understanding and coöperation of educators, hygienists, and the home we can accomplish much.

Ambition and desire are fundamental to the search for health, as for the attainment of any other end, and in the period of school life we can perhaps accomplish most along lines now most neglected; namely, by endeavoring to arouse in high school and college students the desire and ambition for the improvement of the generation that is to be.

DISCUSSION

GEORGE TRUMAN PALMER, DR. P.H., FELLOW A. P. H. A.

Director of Research, American Child Health Association, New York, N. Y.

DR. ROGERS'S PAPER gives us a very clear presentation of the school hygiene situation in this country. We have popular interest in health. We have recognition of the importance of health on the part of educational authorities. We have laws. At least 42 states have acknowledged by statute the desirability of school medical inspection. These are indications of growth and progress.

There is an aspect of this work however which is almost totally undeveloped, and that is the measurement of results. We do not know the degree to which the object of this work, the school child, has profited from all this effort. Has not the time approached when we should seriously tackle the job of checking results?

The business man is accustomed to the taking of an inventory. He wants to know not only how much goods have been sold but what has been the net return in dollars and cents. The aviator wants to know not only how many miles he has travelled and the quantity of gas consumed, but also whether he is keeping to his course. In school health work we ought to know not only how many examinations or nursing visits are made but how much the level of health has been raised as a result of the specific measures used to accomplish this end.

There are at least three rather distinct purposes of school health work: First, there is the protection of the child against the hazards of school life. Education is compulsory, and therefore it would appear only fair to fathers and mothers that the educator should give assurance that every precaution will be taken to prevent attendance at school from endangering health. It is this thought which justifies sanitation of the school plant, watchfulness against the spread of communicable disease, and immunization against such diseases as is practicable. The second objective is the protection of the school investment, by making certain that the pupils for whom educational expenditures are made are in a fit physical condition to receive instruction efficiently. It is this fact that justifies physical examinations and nursing service. A third objective is part and parcel of education, the building of a better informed and more virile citizenry. It is this purpose which justifies health education and physical education.

To measure progress toward the first objective there is needed at least a more precise knowledge of the causes of absence distinguishing between those causes related to health from those not so related. Absence might well be recorded under five distinct headings: A, colds and their complications; B, the specific communicable diseases of childhood such as scarlet fever, measles, diphtheria, etc.; C, other ills and injuries; D, exclusion not because of illness, but because of exposure to others with recognized transmissible diseases; E, causes other than illness or exclusion, such as staying at home through fear of epidemics, visits to relatives, etc.

Measuring the second point involves the development of reliable objective methods for gauging the status of different aspects of physical condition, such as vision, nutrition, hearing, teeth, etc. We have standard methods of water analysis; we need commonly accepted standards for expressing results of school health work.

Let me digress for a moment here to say that in speaking of standards of measurement, I do not mean to imply that children should be standardized or that health programs should be standardized. Mention of the word standardization frequently

provokes an unfavorable reaction. In measuring results, however, there must be objectivity, and this means standardization in terminology and in technic—otherwise comparisons are impossible.

It is the lack of such standards that renders existing reports on physical defects and corrections valueless for comparison. One city reports 10 per cent of children possessing a certain defect. Another city reports 30 per cent. In one place vision is called defective if the 20/20 line cannot be read. In another place a defect is not recorded unless the 20/30 line is not read. Until a defect is defined in precise terms and the manner of determining that defect reduced to standard routine, the resulting figures do not show real differences in the distribution of physical handicaps among children. This type of measurement though difficult is not insurmountable.

The third objective can perhaps best be checked by tests of knowledge, habits, attitudes as well as of strength and physical prowess. Such tests of course tell only part of the story because the lasting success of health and physical education will not be known until school days have long been passed.

It is with the object of contributing to this field of measurement in school hygiene, that the American Child Health Association has recently embarked on an intensive study. Their efforts are directed toward portions of the second and third objectives, the measurement of different aspects of health status and of health knowledge, habits and attitudes.

For a year and a half research has been conducted with children and with examiners in the effort to secure objective, reliable and valid measures. The same children have been repeatedly tested by different people, each working independently. Gradually there have evolved methods proved by actual trial, which will give the same result in the hands of different examiners, which will give the same result a week from today as today, providing the object being examined does not change, and which assure a measure of the thing that it is desired to measure.

In the development of the plan of this research and in the development of the original technic used, the greatest contributor has been Raymond Franzen, Ph.D., a man of wide experience in the field of educational measurement. He has been assisted by physicians, teachers, nurses, dentists, public health workers and others.

Equipped with these testing procedures, the A. C. H. A. has just dispatched three squads of technicians, five members on a squad, to make observations upon from 8,000 to 10,000 fifth and sixth grade children scattered over 70 cities of the country. This will continue during the present school year.

It is the ambition of the association to derive from this experience: First, a knowledge of the differences in certain aspects of health in children, and consequently a better understanding of school health problems. Second, a knowledge of the degree to which certain aspects of health are associated with certain school health activities. Third, a means whereby school authorities can judge progress in health promoting activities. Fourth, information which will be of assistance in laying out a more productive and resultful health program in the schools.

If some of the hopes of the association can be realized from this study, it should be possible for school administrators to discriminate more wisely in the choice of school health activities, to eliminate the unproductive, and cultivate more assiduously the steps that count.

NOTE: The discussion by Harold DeWitt Cross, D.M.D., will appear in the February JOURNAL as a separate article, entitled "Dental Hygiene Aspects of the School Health Problem."

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

THE NEW JOURNAL

WITH this, the first number of its eighteenth year, we present to our readers a new AMERICAN JOURNAL OF PUBLIC HEALTH. In doing so, we are taking an important step in the forward looking program which the American Public Health Association has adopted with respect to its publication activities. The JOURNAL comes to you in a cover of livelier hue and with a new dress of type notable for its beauty and legibility. It is printed on a fine grade of book paper. It is a sewn book, easy to open, easy to hold. It is indeed a new JOURNAL in appearance. But as to well written, soundly scientific text content it is the old JOURNAL. We shall keep the standard as high as ever and exert every effort to raise it.

In this new JOURNAL is incorporated for the first time another periodical, a publication which has made a place for itself in the public health field under notable editorship recently and in the past and always with fine publishing ideals. The American Public Health Association has acquired *The Nation's Health* from the Modern Hospital Publishing Company of Chicago. With this issue, *The Nation's Health* is merged with the AMERICAN JOURNAL OF PUBLIC HEALTH. The names of both will appear on our cover and title pages. The most noteworthy features of both will continue each month.

We welcome to our pages the thousands of readers of *The Nation's Health*. We welcome its advertisers who thereby gain a larger audience and one that completely represents the public health field. We go forward with our banners high and remembering always the words on the Association seal: "And the leaves of the tree were for the healing of the nation."

THE DISMISSAL OF DR. HERMAN N. BUNDESEN

IT HAS BEEN a long time since anything has occurred which has so shocked the public health officers of the United States, or done so much to upset the morale of those engaged in health work, as the dismissal of Dr. Herman N. Bundesen as Health Commissioner of Chicago. Some suspected that this would occur soon after the election of Mayor Thompson, but as the months went by, everyone felt that he had recognized the fitness of things by retaining a health officer who has been distinguished by his beneficent activities. We know of no charges which have been made against him. On the other hand, we know that he has received the highest commendation from the best class of physicians in Chicago, and in addition, has been the recipient of a number of distinguished honors, such as the Lawson prize, which was given on account of his good work in saving the lives of infants and insistence on clean milk, and an honorary degree by his alma mater conferred largely because of his record as a health officer. He was also elected President of the American Public Health Association.

We know further that he has surrounded himself by a group of unusually efficient men; that every department in his office was headed by an expert; and that the entire health department of Chicago has been a model in organization as well as accomplishment.

The value of experience has apparently been thrown to the winds. The new appointee has been a resident of Chicago only since 1922. There is no evidence that he has ever had any training in public health work, and the only experience of this kind which is noted is that he was appointed by the mayor as Chairman of the Medical Section of the Chicago Flood Control Conference. While we wish him every success, it is perfectly evident that he lacks public health training as well as experience, and we judge of this by what purports to be an official document concerning him. His entire training, apart from that which the usual medical student gets, seems to have been in surgery, and he is spoken of as a "surgeon and surgical consultant."

In this connection, we wish to point out that the medical degree does not of itself fit anyone to be a health officer. It requires special training and a certain amount of experience, for which we believe the medical degree is a great assistance, but which is very far from making one proficient in public health work.

This JOURNAL has always stood, and we hope always will stand, for tenure of office, so that a competent health officer and his assistants may be assured of permanency. Politics is the most baneful influence to which public health work in this country is subject at the present time. It has been responsible for disasters in the past, and we believe

is still the chief cause of many of the shortcomings which those interested in public health work recognize.

While the new health officer has, according to the newspapers, denied that he expects to discharge any of the personnel at present in the department, he has also said that if the mayor wished to appoint any friends, he would try to coöperate.

We hope that nothing we have said will be considered personal. It is not intended to be so, but unquestionably a most deplorable situation has come about, and no one on the outside knows what to expect.

Chicago is one of our largest and most important cities, and what happens in health matters there deeply concerns the entire United States.

This JOURNAL is interested in building up public health as a profession, and every such occurrence sets back the good work which has been going on for a number of years.

THE BAD MILK IN OUR SMALL TOWNS

STARTLING and shocking are the facts revealed by a recent survey of market milk in the small towns of the United States. In our towns and cities having populations of less than 25,000 the milk seems as a general rule to be dirty and contaminated. According to a report of the American Child Health Association,¹ which has coöperated in investigations in 19 states, the milk supplies of small towns are high in bacteria, seldom come from tuberculin tested cattle, and are rarely pasteurized.

In 117 small towns and cities studied, an average of 25 per cent of the milk supplies examined contained 200,000 or more bacteria per c.c., while an average of 40 per cent had 100,000 or more bacteria. Fifty-one cities gave a positive test for *B. Coli* in 50 per cent or more of the supplies tested and 21 cities gave such a positive test in 75 per cent or more. Physical standards used for showing dirt revealed that most of the milk was actually dirty. In only two places could 75 per cent of the supplies be classed as "clean" or even "fairly clean."

Not one of the 117 towns and cities had 90 per cent pasteurization, and 97 of these communities had no pasteurization at all. These facts are in direct contrast to the large cities of the country, as more than half of the cities with a population of 100,000 or greater now have 90 per cent or more of their milk supplies pasteurized.

These significant facts call for strenuous efforts on the part of sanitarians to assure a better and purer supply of the best of foods of man.

Campaigns to induce people to drink milk are valuable, because good milk is the one nearly perfect nutriment, but along with these cam-

paigns must go assiduous endeavors to secure clean and safe milk. There are apparently many parts of the country where it is wiser to use some concentrated form of milk, such as the dried product, than the extremely dangerous fluid milk supply. The milk furnished in our large cities, at least that supplied by the more reputable companies, may be drunk with impunity, but until more adequate and intensive methods have been taken to improve the milk supplies of small towns, their use as a beverage is evidently fraught with some hazards.

¹ Crumbine, S. J. and Holland, D. F. Survey of Small Town Milk Supplies, *Child Health Bulletin*, Nov., 1927.

SANITATION OF WATERWAYS

THE newly constituted Board of Public Health Engineers of the Ohio River Basin* is believed to be the first board of its kind in this country. Its creation points clearly to further improvement in the sanitation of our waterways.

Our methods of attacking the stream pollution problem are varied, to say the least. Some consider coöperation with industry as the solution; others maintain that the results of research will prove to be the explanation; while a third group adheres closely to strictly regulatory measures. It would seem that the combining of all three of these courses in such balance as to be applicable to the needs in each separate instance would be the best procedure.

From the administrative standpoint, authority for control has been lodged in some cases in a single regulatory body such as a state health department, and in others, in a new group like the Pennsylvania Sanitary Water Board having diversified interests. However, the general tendency appears to be toward the formation in states of such boards or committees as will include within themselves all the different interests concerned in the purity of the waters. The policies of these administrative bodies differ. Some set up rigid control to abate or, at least, diminish all pollution; some, under a plan of stream classification, propose that certain waterways should be devoted to the reception of wastes, while other streams should be maintained in their present state of purity.

The trend in waterways sanitation in this country resembles that in England which has had a hundred or more years of experience with this question. The chemist¹ of the West Riding Rivers Board has pointed out that in England there has been an improvement in the waterways of the older industrial areas due to remedial measures. On the other hand, he indicates that in the newer areas conditions are

* See page 104.

becoming worse on account of the increase in the amount of sewage and industrial wastes. His proposals for the improvement of stream conditions are: (1) the survey and classification of streams and watershed areas, and (2) the formation of additional rivers boards. He also suggests that liquid trade wastes be admitted to public sewers and that increased research in fundamental problems of stream pollution and sewage treatment be provided.

Apparently waterways sanitation has lagged in England also, because of divided authority. Lord Mildmay of Flete¹ points out "how the problems of pollution have constantly engaged the attention of Royal Commissions, of Select and Departmental Committees, of scientific bodies and of other institutions, for more than half a century and how all have agreed that some form of central authority is absolutely necessary in view of the lack of coördination which exists amongst those bodies that have control of rivers—lack of coördination which has resulted in confusion and indifference."

In reply the Lord President of the Council, the Earl of Balfour, stated that there were two problems to be considered; namely, an administrative one and a scientific one. He advised the House of Lords that, to cope with the first, the government had appointed an advisory committee representing the departments concerned and having as chairman Sir Horace Monro and, to handle the second, a board,* with Dr. H. T. Calvert, M.B.E. as chairman.

From the foregoing comparison, it appears that, in many ways, practices related to administrative and scientific attack of the stream pollution problem in England and in this country are more and more approaching parallel lines. This division of the regulatory and research problem would seem to be a wise example to follow in this country.

*From the context of the unrevised report it appears that this group is called the Water Pollution Research Board.

BACK TO BEGINNINGS

THE National Tuberculosis Association has taken a wise step in the inauguration of a country-wide early diagnosis campaign, as outlined elsewhere in these pages.

The hope of cure in tuberculosis depends upon the early discovery of the disease. There is abundant evidence, both from clinical observation and the post-mortem table, that of all the chronic diseases, tuberculosis is probably the most easily healed. Many authorities

agree that if the disease is discovered in its incipency, or in its "minimal stage," to use a more scientific term, as high as 85 per cent of those placed under proper treatment will be restored to working efficiency.

But while these truths have been vigorously proclaimed for twenty years or more, there still seems to be an apathy, both on the part of the public and the medical profession, to the significance of the early recognition of tuberculosis. The disease is so insidious in its beginnings and resembles in its minimal stages so many pathological conditions other than tuberculosis, that detection before serious lesions have resulted in the lungs is extremely difficult.

Study of early cases on record in sanatoria for the treatment of the disease and in the files of health departments, indicate a need for concentrated effort along the lines proposed by the national, state and local tuberculosis associations to be carried on during next March. Less than 20 per cent of the pulmonary cases which go to the average tuberculosis sanatorium are in the real early, curable stages of the disease.

Plunkett's study of tuberculosis reporting shows that almost one-half (44.7 per cent) of the cases which terminated in the death of the patient were either not reported at all (14.1 per cent) or were reported after death (30.6 per cent). Alice M. Hill's studies in Fargo and elsewhere show that from a follow-up of physicians' records of tuberculosis there is much more diagnosed tuberculosis in any community than is ordinarily believed to be the case. On the basis of experience showing that about one-third of all cases of tuberculosis discoverable in a community are usually unknown before the adoption of intensive methods of case finding, the National Tuberculosis Association estimates that there are approximately 270,000 active but unknown cases of tuberculosis in the United States at the present time. It is these cases that the early diagnosis campaign seeks to discover.

We commend, therefore, the activities of the national, state and local tuberculosis associations in going back to beginnings and in laying emphasis upon the diagnosis of tuberculosis.

ASSOCIATION NEWS

PROCEEDINGS OF GOVERNING COUNCIL AND EXECUTIVE BOARD

DURING the Fifty-sixth Annual Meeting of the Association at Cincinnati, O., October 17-21, there were three meetings of the Executive Board. The Governing Council met five times, the last being a meeting of the newly elected Governing Council. A digest of the minutes of these meetings and reports of the committees are published here for the information of the Fellows and members of the Association.

GOVERNING COUNCIL PROCEEDINGS OCTOBER 17

Local Committee—William H. Peters, M.D., Chairman of the Local Committee offered the hospitality of Cincinnati and expressed the hope that the meeting would measure up to the high ideals of the Association, and that everyone would find it pleasant and profitable.

Report of the President—This brief report was read by the Executive Secretary and referred the Council to the minutes of the three Executive Board Meetings held during the year.

Report of the Treasurer—Louis I. Dublin, Ph.D., Treasurer, called attention to the growth of the Association as measured by the income and expenditure and increase in assets.

Report of the Executive Secretary—A 5-year report was presented in abstract. (The full report will be sent to members.)

Committee on Administrative Practice—The report presented by Professor C.-E. A. Winslow was accepted. (This report will be published in a later issue of the JOURNAL.)

Committee on Dairy Products—A progress report was presented by William H. Park, M.D., for Professor Henry C. Sherman, Chairman. The final report of the committee will be based on a report made in October by Leslie C. Frank to the U. S. Public Health Service, after several years' study.

Committee on Cancer—This report published in the November, 1927, issue of the JOURNAL, was accepted and the committee continued.

Federal Health Legislation—Some progress has been made in the movement for the coördination of the health activities of the national government, according to the report of James A. Tobey, Dr.P.H., secretary of the committee. At the hearings on the Parker Bill, the American Public Health Association was represented by Herman N. Bundesen, M.D., James A. Tobey, Dr.P.H., George W. Fuller and others. The Parker Bill has been endorsed by a number of influential national organizations. The Governing Council endorsed the recommendations that the Association advance the interests of the Parker Bill in every legitimate way at the 70th Congress of the United States. It was voted to continue the committee.

Committee to Speak for the Association on the Parker Bill—Herman N. Bundesen, M.D., Chairman, recommended that this committee be discontinued and its work transferred to the Committee on Federal Health Legislation. This recommendation was accepted.

Census of Public Health Workers—A plan for making a census of public health

workers outlined by the Executive Secretary was approved. Upon the recommendation of the Executive Board a committee for directing the census will be appointed by the Governing Council.

Election of Fellows—Thirty-eight applications for Fellowship were approved.

OCTOBER 18

Registration Fee for Members of the Association—A proposal to charge a registration fee for members attending the annual meetings was tabled.

Petitions of State Health Societies for Affiliation—The applications of the Ohio Society of Sanitarians, the Northern California Public Health Association and the Southern California Public Health Association were approved. The applications of the Connecticut Public Health Association and the South Carolina Public Health Association were approved subject to these societies complying with the membership requirements.

Committee to Coöperate With the Director of the Census—The President was authorized to appoint a committee of three to act as an advisory committee to coöperate with the Director of the Census in regard to vital statistics.

Editorial Committee—Homer N. Calver, managing editor, reported that the JOURNAL will appear in a new format.

Commissioning of Sanitary Engineers—In reporting for this committee, George W. Fuller, Chairman, said that \$25,000 had been restored to the budget of the U. S. Public Health Service to cover traveling expenses of engineers and to transport their families. The committee was continued.

Committee on Eligibility—The Executive Secretary reported that the applications of 3 societies for affiliation had been approved and that of 51 applications for Fellowship, 38 had been approved.

Council on Standards—The report which included a proposed policy and

scope of activities of the committee and routine procedure for Association committee reports and Section committee reports was accepted.

Annual Meeting Policy—The report of the Finance Committee to which this matter had been referred by the Executive Board was accepted. The report recommended that the continent be divided into 7 districts in which the Association may meet in rotation.

A list of cities in each district in which annual meetings could be held was submitted and a plan for selecting the annual meeting cities was suggested.

The executive office was instructed to assist in the development of regional meetings where desired by the members.

OCTOBER 19

Committee on Industrial Health Service—The recommendations read by W. S. Rankin, M.D., Chairman, were accepted; namely,

First, that the committee be continued as a sub-committee of the Committee on Administrative Practice.

Second, that the membership of the committee be increased.

Third, that the Sub-committee on Industrial Health Service prepare a form for the collection of the essential data with respect to health conditions and health services of industries.

Fourth, that industries be served as a part of the general program of community health service.

Committee on Resolutions—The Resolutions, read by Professor E. O. Jordan, as Chairman, were accepted. (See November, 1927, JOURNAL, pp. 1162-1164.)

Election of Officers—By written ballot, the following officers were elected for 1927-1928: President, Herman N. Bundesen, M.D.; First Vice-President, George W. Fuller; Second Vice-President, William H. Peters, M.D.; Third Vice-President, James Roberts, M.D.; Treasurer, Louis I. Dublin, Ph.D.

Collection and Maintenance of Information Concerning Health Officers—A suggestion for collecting and maintaining for health officers of the country, accurate information concerning costs, equipment, staffs, plans, etc., of health centers was referred to the Committee on Administrative Practice.

Association of School Physicians—A letter was read from the Association explaining its purpose and saying that the members who are also members of the American Public Health Association will endeavor to increase the membership of the Child Hygiene Section and desiring that two sessions be devoted to school medical service at the next annual meeting.

Advance Meetings of Executive Board—It was voted that so far as practicable individual members of the Governing Council be advised in advance of the major policies to be considered by the Executive Board.

OCTOBER 20

Change of Name of Food and Drugs Section—It was voted to amend the by-laws of the Food and Drugs Section changing its name to Food, Drugs and Nutrition.

Annual Meeting City for 1928—By written ballot Chicago was chosen as the annual meeting city for 1928.

Elective Councilors—Members elected to the Governing Council, terms expiring 1930, were: John W. Amyot, M.D., George W. Bigelow, M.D., Walter H. Brown, M.D., Herman N. Bundesen, M.D., Edwin O. Jordan, Ph.D., W. S. Leathers, M.D., John E. Monger, M.D., Matthias Nicoll, Jr., M.D., Professor C. E. Turner and C.-E. A. Winslow, Dr.P.H.

OCTOBER 20

New Governing Council Meets—The meeting of the new Governing Council was called. The only business transacted was the election of the following mem-

bers to the Executive Board, terms expiring 1929: A. J. Chesley, M.D.; John E. Monger, M.D., and Professor C. E. Turner.

EXECUTIVE BOARD MINUTES

OCTOBER 16

Report of Association Committees—(See digest of Governing Council Meeting minutes on page 74 of this issue.)

Public Health Year Book—The plan of this book presented by Arthur Tomalin, was referred to the Finance Committee for further study of its practicability and means of underwriting it.

New Publication—In principle the establishment of a new publication was approved. The executive office was instructed to negotiate for the purchase of *The Nation's Health*.

Reports of Representatives and Delegates of the Association—These reports were accepted.

Delinquent Members—The names of 136 members and Fellows delinquent in payment of dues for 12 or more months were stricken from the Association membership roll.

Membership Campaign and Census of Public Health Workers—A plan for an intensive membership campaign and a census of public health workers was approved and a sum was voted to defray expenses of this project. (See Governing Council proceedings on page 74 of this issue.)

Proposal from the American Institute—The Board expressed its sympathy with the projects of the Institute and recommended that the Institute seek the coöperation of the American Association for Medical Progress.

Proposal from Cleanliness Institute—It was voted to ask the President to appoint a committee on cleanliness and health with power to confer with section officers, the Cleanliness Institute and other bodies, and report back to the Executive Board.

National Tuberculosis Association—The campaign planned by the National Tuberculosis Association for the early diagnosis of tuberculosis was approved and coöperation promised.

Representatives to American Association for Advancement of Science—The President was authorized to appoint delegates from the Fellowship to represent the Association at the meeting of the American Association for the Advancement of Science at Nashville, Tenn., December 26-31, 1927.

AMERICAN CHILD HEALTH ASSOCIATION
TO MEET AT SAME TIME AS AMERICAN
PUBLIC HEALTH ASSOCIATION

THE American Child Health Association of which Herbert Hoover is president, will hold its next annual scientific meeting simultaneously with the Fifty-seventh Annual Meeting of the American Public Health Association and at the same place. This decision was made at the quarterly session of the Executive Committee of the American Child Health Association, December 2, 1927, according to a communication received from S. J. Crumbine, M.D., General Executive.

The A. C. H. A. will hold joint meetings with the Child Hygiene Section and the Public Health Nursing Section of the A. P. H. A., adding considerably to the strength and value of the sessions of these two sections particularly.

This plan was favorably accepted at the meeting of the Executive Board of the American Public Health Association held at the executive office, December 10.

The joint meeting will be held in Chicago, Ill., the week of October 15, with headquarters at Hotel Stevens.

STATE NEWS

TEXAS

Tenth Annual Waterworks School—The school will be in Houston, January

23-27 under the joint auspices of the Texas Section of the Southwest Water Works Association, Texas State Department of Health and the City of Houston. James H. B. House, Houston, is general chairman and W. S. Mahlie, Fort Worth, is director of the school.

Among the lecturers at the school will be: George W. Fuller, consulting engineer, New York, N. Y.; Jane Rider, state sanitary engineer, Arizona; Frank Bachmann, sanitary engineer, Chicago, Ill.; M. Z. Bair, state sanitary engineer, Little Rock, Ark.; Ernest Boyce, state sanitary engineer, Lawrence, Kas.; Arthur Brown, sanitary engineer, Chicago, Ill.; L. H. Enslow, research engineer, New York, N. Y.; Paul Fox, state sanitary engineer, Santa Fe, N. M.; and August V. Graf, city water superintendent, St. Louis, Mo.

Dr. J. C. Anderson, state health officer, is chairman of the Program Committee. Headquarters will be at the Rice Hotel.

Dr. Carrick's Appointment—Dr. Manton M. Carrick, city health officer of Dallas, has been appointed a director of the National Committee for Mental Hygiene.

Pampa Adopts Milk Ordinance—Pampa has adopted the Standard Milk Ordinance recommended by the Texas State Department of Health.

Resolutions of State Sanitarians—Among the resolutions adopted at the recent meeting of the State Association of Sanitarians held at Houston were:

That the Texas State Medical Association investigate the New Jersey plan for licensing health workers with the view of its adoption in Texas;

That arrangements be perfected for holding regional milk sanitation meetings in different parts of Texas in locations conducive to satisfactory attendance in order that the message of the benefits of sanitation may be brought direct to the people.

That inasmuch as the National Dairy Show is one of the most effective mediums for the stimulation of dairying and best business

methods, that efforts be made to bring this show to Texas in the near future.

Better Health Special Tours Texas—

The Better Health Special, a coöperative accomplishment of the officials of the Missouri Pacific Railroad and the Texas State Health Department under the direction of Dr. J. C. Anderson, State Health Officer of Texas will visit 75 Texan cities. The train, carrying a health demonstration car, diner and observation Pullman for the lecturers and attendants will leave Longview, January 16.

Education in public health will be featured in the program of the Better Health Special. Rules of sanitation, malaria and typhoid control and other public health measures will be taught by lectures, motion pictures and exhibits. The train will carry an exhibit of modern dairy equipment. The program is arranged for adults and school children.

Dr. Durham, State Registrar, Dead—

Dr. C. E. Durham, director, bureau of vital statistics, Texas State Department of Health, died in Austin, November 30, after a short illness. During his 4 years as state registrar, Dr. Durham had accomplished much toward bringing Texas into the birth registration area.

Dr. Durham was a graduate of the University of Texas and the Texas State Medical School. For 24 years he was engaged in the private practice of medicine in Texas.

MICHIGAN

Michigan Public Health Association

Meets—The annual meeting of the Michigan Public Health Association will be held in conjunction with the Michigan Department of Health, January 11, 12, 13.

Communicable Disease Control, County Unit Plan, and the Present Status of Scarlet Fever are subjects to be discussed, the last to be presented by

Guy L. Kiefer, M.D., State Health Commissioner.

NEW JERSEY

New Jersey Sanitarians Meet—Incorporation of the New Jersey Public Health and Sanitary Association was provided for in the new constitution and by-laws adopted at the Fifty-third Annual Meeting of the New Jersey Sanitary Association held at Princeton, N. J., December 2 and 3. The following officers were elected:

President, B. S. Pollak, M.D., Secaucus, N. J.; First Vice President, B. H. Obert, Asbury Park, N. J.; Second Vice President, H. B. Costill, M.D., Trenton, N. J.; Third Vice President, D. C. Bowen, Trenton, N. J.; Chairman of the Executive Council, Samuel B. English, M.D., Glen Gardner, N. J.; Representative to A. P. H. A., Edward M. Guion, M.D., Atlantic City, N. J.; Alternate, B. H. Obert, Asbury Park, N. J.

D. C. Bowen, director of health of New Jersey, and chairman of the executive council, presided at the opening meeting. Chester G. Wigley, C.E., Atlantic City, retiring president, in his address spoke on "Recent Progress in Sanitary Engineering Work in the State of New Jersey." Following a paper on "Pre-School Clinics" by Julius Levy, M.D., Consultant, Bureau of Child Hygiene, New Jersey State Department of Health, there was a discussion by E. I. Cronk, M.D., Health Officer of New Brunswick.

The influence of health departments in diphtheria control was discussed by Henry B. Costill, M.D., Trenton; F. P. Lee, M.D., health officer, Paterson; J. Bennett Morrison, M.D., Secretary, Medical Society of New Jersey—all representing the committee on the state wide anti-diphtheria campaign.

The paper "Relation of the Physician to the Patient from a Public Health Standpoint," by Walter Ponder Conaway, M.D., Atlantic City, president of the New Jersey Medical Society, was discussed by A. S. Stone, M.D., director of public health, Camden. Joseph R.

Morrow, M.D., superintendent, Bergen County Hospital, Ridgewood, led the discussion on "After Effects of the Use of Serums in the Human Economy."

W. W. Peter, M.D., Associate Secretary of the A. P. H. A. addressed the delegates to the meeting of the Health Officers Association of New Jersey, which was held December 3 in conjunction with the meeting of the sanitarians. A. S. Fell, M.D., presided.

WEST VIRGINIA

West Virginia Public Health Association—How non-professional workers can function in a state-wide health program was the subject of one session of the second annual meeting of the West Virginia Public Health Association, held at Morgantown, November 21-24. At this meeting of the Lay Section of the association the possibility of dovetailing their programs into the community health program was considered from the point of view of the churches, men's and women's clubs, sociological department and the farm extension division of the University of West Virginia, the rural school teacher, and the nutritionist.

Another session was given over to the Health Officers Section and the Public Health Nursing Section.

David Littlejohn, M.D., in his presidential address spoke on "West Virginia's Health Problems." A report of the milk survey in West Virginia was given by Clarence E. Smith, Associate Milk Specialist, U. S. Public Health Service; and H. M. Newton, M.D., federal officer in charge of bovine tuberculosis in West Virginia talked on "Tuberculin Testing of Cattle as a Factor in Producing a Safe Milk Supply."

Josephine Baker, M.D., of New York City spoke on the safeguarding of lives of mothers and babies in West Virginia and Miss Miriam Birdseye of the U. S. Department of Agriculture talked on

"The Nutrition Program as Related to Public Health."

The association passed a resolution favoring the requirements of the Standard Milk Ordinance as recommended by the U. S. Public Health Service and favoring its adoption by the various municipalities of West Virginia.

Another resolution passed endorsed the correlated Country Life Program and recommended that the heads of departments of Agriculture Extension Service, the State Department of Health, the Division of Rural Schools and the State Department of Agriculture meet for the purpose of planning a Country Life Program to be published in bulletin form for the year 1928.

A health exhibit was held under the direction of Miss Dorothea Campbell, director, Division of Public Health Education, West Virginia State Department of Health.

W. T. Henshaw, M.D., Charleston, was elected as representative on the executive council of the A. P. H. A. The officers elected for 1928 were:

President, David Littlejohn, Charleston; 1st Vice-President, J. G. Pettit, M.D., Hopemont Sanitarium; and 2nd Vice-President, W. H. McLain, M.D., Commissioner of Health, Wheeling. Councillors: Marian D. Bell, Fairmont; Gertrude Eckhardt, Keyser; A. L. Oilar, M.D., Glenville; Grace Bauer, Parkersburg; Elizabeth C. Lowry, Logan; and John Thames, M.D., Charleston. Representative on Executive Council, A. P. H. A.: W. T. Henshaw, M.D., Charleston. Officers of the Lay Section elected were: President, Mrs. Dorsey R. Potter, Clarksburg; Vice-Chairman, Mrs. Alice C. Boomsliiter, Morgantown; and Secretary, Mrs. John Stuart, Clarksburg.

Homer N. Calver, Executive Secretary and W. W. Peter, M.D., Associate Secretary of the A. P. H. A. attended the meeting. Dr. Peter was one of the speakers.

DR. JONES REAPPOINTED

Charles Hampson Jones, M.D., for 31 years in the service of the Baltimore, Md., health department, has been reap-

pointed health commissioner of that city. A testimonial dinner was given for Dr. Jones on December 1 by a group of professional colleagues, and he was pre-

sented with a gift of \$500 in gold in appreciation of his conscientious and excellent services in the interest of the public's health. He is a Fellow of the A. P. H. A.

A. P. H. A. CHICAGO ANNUAL MEETING

BECAUSE of the action of Mayor Thompson of Chicago in curtly dismissing from office Health Commissioner Herman N. Bundesen, to replace him with the mayor's personal physician, widespread and bitter protest was received by the Executive Board of the American Public Health Association at its last meeting against holding the Fifty-seventh Annual Meeting of the Association in Chicago next October.

The protest took the form of a resolution offered by a large group of Fellows and members of the Association

from different parts of the country in which it was said—"It is an affront to the public as well as a potential danger when the health officials are selected solely by the whim of political favoritism. Only well qualified sanitarians should be appointed to responsible positions in public health administration."

After lengthy consideration of the protest the Board, largely through the interposition of Dr. Bundesen, decided to go ahead with its plans for the meeting in Chicago.

BOOKS AND REPORTS

Federal Health Administration in the United States—By *Robert D. Leigh*, *A Barton Hepburn Professor of Government, Williams College. New York: Harper, 1927. 687 pp. Price, \$5.00.*

Here is a book which ought to be read by every one in any way interested in the important problem of federal health correlation, and it could be read to advantage by all who are concerned with public health administration. It is a thorough and scholarly treatise on the development, scope, and present functions of the health organization of our national government, a subject which has recently come to the fore as a result of the surveys and endeavors to secure Congressional action for the more effective coördination of these health activities. As a climax to his descriptions and discussions, the author offers a plan for the centralization of the federal health activities, proposing a new department of education and health, comprised of the Public Health Service, the Children's Bureau, and the Bureau of Education. In many respects, the principles which he sets forth in connection with the proposed reorganization correspond with the Parker bill in their essential features.

This book deals with federal health activities on a functional basis, rather than by the scheme of outlining in detail the activities of each of the many bureaus doing health work. It is, in fact, a philosophical discourse as well as a factual presentation. After introductory chapters on the evolution of American public health organization, and the federal health powers under the commerce, taxation, and other clauses of the Constitution, the author discusses the na-

tional medical care of merchant seamen; medical care and preventive medicine in the army and navy; the same for World War veterans, Indians, territorials and other wards; national quarantine against epidemic diseases; national health regulation of commerce; and such miscellaneous matters as vital statistics, scientific investigation, and education. He concludes with chapters on federal stimulation and aid; public health and the federal problem; the attempts at national health reorganization; public health and national administrative reorganization; and a particularly useful chapter on the personnel problem. Once or twice there seems to be a slightly undue amount of space devoted to venereal disease control.

The book is written in a readable and clear style. It is exceptionally well printed and arranged, though the notes would have been much more useful if they had been placed on each appropriate page, or at least at the end of each chapter, instead of having been assembled at the back. There is an excellent bibliography and also a good index. This important addition to the Harper Health Series is a notable accomplishment with respect to both form and substance.

JAMES A. TOBEY

Personal Health—By *Emery R. Hayhurst, M.D., Professor of Hygiene in Ohio State University and Consultant in Industrial Hygiene to the Ohio State Department of Health. New York: McGraw-Hill, 1927. 278 pp. Price, \$3.00.*

Dr. Hayhurst is widely and favorably known to the public health profession, and this book should add still further to his recognition as a sound and constructive scientist and a progressive sanitarian.

ian. He has undertaken the unusual and worthwhile in preparing a book to "serve the busy person in shop or office as a health guide and a medical advisor." His experience and standing in the field of industrial hygiene is unexcelled and he has drawn upon this wide experience for innumerable incidents and illustrations which add point and interest to the book.

The historical approach is used to introduce the discussion of health and health practices. The body of the book divides the subject of hygiene upon the following bases: digestive system, skin, breathing system, circulatory system, kidney, bladder and sex organs, muscles, bones and joints, nervous and mental health, eyes, ears, glands, cancer. There follow a chapter on the War Upon the Microbe, and a brief chapter containing general advice.

The book is well printed and attractively bound. The 64 photographic illustrations are well chosen. The English is fresh and to the point,—not classical.

The book should be useful to employers, foremen and workers. It deserves to be read. Teachers of adult classes or industrially employed groups should find this a clear, understandable and useful reference or text. C. E. TURNER

The Principles of Sanitation—By C. H. Kibbey. Philadelphia: F. A. Davis Co., 1927. 354 pp. Price, \$3.50.

This book has been prepared as a practical handbook for public health workers, especially for sanitary inspectors who may or may not have had technical training. The book is based upon a series of lectures and demonstrations given by the author to inspectors.

Chapters dealing with the cause and prevention of communicable diseases are largely non-technical in make-up, but give the essential facts for the group of readers for whom the book is primarily designed. As minor criticisms, the danger of transference through "fomites"

perhaps receives greater emphasis than modern experience now justifies. Unfortunately, "ptomaine poisoning" is used without stating that this term is a misnomer; and the section dealing with food infections is somewhat brief in comparison with similarly important problems. But the book, as a whole, seems well balanced.

The third section, on modern methods of rural sanitation, appeals to the reviewer as the most valuable portion of the book. A section on the prevention of occupational diseases is also of practical value to inspectors and concludes this useful volume, which should prove helpful to many health officers, public health nurses and sanitary inspectors.

IRA V. HISCOCK

Preventive Medicine—By Mark F. Boyd, M.D., 1927.

Influence of Sun Rays on Plants and Animals—By C. G. Abbot. Illus., 1927.

Cold Light—By E. Newton Harvey, Ph.D., 1927.

The History of Organic Evolution—By John M. Coulter, 1927.

The Mosquito Fish (Gambusia) and Its Relation to Malaria—By David Starr Jordan. Illus., 1927.

The Parasite Element of Natural Control of Injurious Insects and Its Control of Man—By L. O. Howard, 1927.

William Bateson—By T. H. Morgan, 1927.

These pamphlets ranging from 5 to 20 pages, are reprints from the Smithsonian Institute Report for 1926, and have been prepared by the U. S. Government Printing Office, Washington, D. C., each bearing the Institute seal.

An Elementary Laboratory Guide in General Bacteriology—By *Harold J. Conn, Soil Bacteriologist, New York Agriculture Station: Chairman Committee on Bacteriological Technic, Society American Bacteriologists. Baltimore: Williams & Wilkins, 1927. 165 pp. Price, \$3.00.*

The author's purpose as stated in the preface has been primarily to furnish a laboratory guide to accompany *Bacteriology*, by H. W. Conn and H. J. Conn; but he has given us a manual that should be welcomed by instructors in elementary classes in general bacteriology. The author is eminently qualified to appreciate the needs of the instructor as well as the student and has provided a guide in the general methods that constitute a foundation of both medical and agricultural bacteriological technic.

The book contains chapters on molds, preservatives, germicides and milk. An appendix has been added giving media and staining formulae, reference to literature on stains, and a brief discussion of hydroden-ion concentration. There is excellent material in this little book for demonstrations in applied bacteriology and it offers a valuable guide for instructors in bacteriology in nurses' training schools and technical schools.

C. C. YOUNG

Municipal and Rural Sanitation—*Victor M. Ehlers, C.E., and Ernest W. Steel, C.E. New York: McGraw-Hill, 1927. 448 pp. Price, \$4.00.*

"As modern environment has become more complex, so has sanitation necessarily come to include a wider range of activities." Recognizing this fact, the scope of this book has been made comprehensive. The initial chapter explains communicable diseases. It is followed by discussions of excreta disposal, both with and without water carriage and then 50 pages are devoted to water, its treatment and the protection of its sources.

Next there are treated such subjects as refuse collection and disposal; the characteristics of mosquitoes, their control and the organization of campaigns against them; the control of flies and rodents; the sanitation of milk and other foods, and of schools, swimming pools, and tourist camps; housing with related chapters on plumbing, ventilation and lighting; and industrial hygiene.

In a miscellaneous chapter, hookworm and rabies control, comfort stations and barber shop sanitation are covered. The concluding chapters cover disinfection, vital statistics and public health organizations. In the appendix, representative ordinances on privies, mosquito control and milk sanitation are given.

On the whole, the treatment of the subjects is practical and there are numerous illustrations and diagrams. The book can be used as a text and should prove useful to sanitarians, city officials, inspectors and the like.

ARTHUR P. MILLER

The Microscopy of Drinking Water—By *George Chandler Whipple, Late Gordon McKay Professor of Sanitary Engineering, Harvard University. Revised by Gordon Maskew Fair, Assistant Professor of Sanitary Engineering and Melville Conley Whipple, Assistant Professor of Sanitary Chemistry, Harvard University. (4th ed. rev.) New York: Wiley, 1927. 586 pp. Price, \$7.00.*

A book which has for nearly thirty years been a standard text and which has gone through four editions, needs little comment. Its reputation has been established. In regard to the present edition, it would be necessary only to state that it maintained the high type of excellence shown by the former ones, except for the fact that in the meantime we have had to lament the death of Professor Whipple; so the revision has been made by the Assistant Professor of San-

itary Engineering, and the son of the original author, who is Assistant Professor of Sanitary Chemistry.

The extension of the science to which this book is devoted has necessitated its enlargement and the addition of new chapters. Among these that on "Self Purification of Streams" should be especially mentioned. It is of great interest scientifically and has perhaps been too much overlooked as a practical aid in the past. The authors acknowledge assistance in the revision of certain chapters by men whose names assure us of accuracy and completeness.

The book is abundantly illustrated throughout, but mention must be made of the nineteen colored plates, which are of unusual excellence. A special index of the organisms shown is provided, and in the body of the book, sixteen keys are given to aid in their recognition.

Unquestionably this new edition will be welcomed by all interested in water examination, and like the others, it will take its place as a standard book of reference. The make-up of the book is of the usual high class which characterizes the output of the firm which has produced it.

M. P. RAVENEL

Handbook on Positive Health—
Women's Foundation for Health, 370
Seventh Avenue, New York, N. Y.
Price, \$1.50.

The 1928 revised edition includes two new chapters of remarkably fresh and practical material, one from Mary Swartz Rose, Ph.D., Teachers College, Columbia University, on food values; and the other from Lillian M. Gilbreth, Ph.D., Consulting Engineer, on the balancing of work and rest.

The contributors to the first edition, appearing also in the second, are: Professor E. V. McCollum, Johns Hopkins University, "Nutrition in Relation to Health"; Walter B. Cannon, M.D., Harvard Medical School, "The Heritage of

Life"; William A. White, M.D., St. Elizabeth's Hospital, Washington, D. C., and Jessie Taft, Ph.D., Department of Child Study, Philadelphia, Pa., "Mental Health"; and E. C. Lindeman, New York School of Social Work, New York, N. Y., "Recreation." The interpretation of the health examination blanks, both medical and physical, and a chapter on good body mechanics are also carried from the first edition.

E. H.

Rebuilding the Child. A Study in
Malnutrition—By Dr. Frank How-
ard Richardson. New York: Putnam,
1927. 319 pp. Price, \$2.00.

Dr. Richardson's new book on malnutrition is essentially practical. He considers the child as a whole, and the methods he advocates are described in an able and concise manner. These methods are based on sound principles and on his experience in private practice, in hospital clinics and in his own home rather than on current fads.

The author distinguishes two stages of fatigue and he places this factor at the head of that group of signs and symptoms called "malnutrition." This condition must be considered as a clinical entity. The causative factors of this condition are analyzed carefully and evaluated in a convincing way as a preliminary step to the methodical attack upon them in the treatment by which they may be combated and the child improved physically and mentally. The same methods help to maintain the child's health as near as possible at his individual optimum of function. The use of the height-weight-age relationship as one of a number of criteria of optimal physical fitness, is sane and in accord with the best medical practice. This aspect of physical fitness has been much abused by some non-medical workers having too limited a conception of the problem at hand.

Malnutrition cannot be cured by a

proper diet list alone, and the reason this is true is convincingly explained in Dr. Richardson's book.

Every parent and many physicians will profit by considering carefully the chapters on "fatigue," "faulty food habits," "school strain," "family strain," and the intimate relationship between "mentality" and "malnutrition."

It is made perfectly clear by the author that persistent effort on the part of the parent, with the child under periodic examination and supervision, treatment along the lines suggested, is productive of successful results in varying degrees, in a large percentage of cases. The author also states that some malnutrition cases do not seem to respond to any mode of treatment and are baffling and at times discouraging to those who are endeavoring to improve the patient's condition.

Dr. Richardson is frank and sincere and his explanations are clear and convincing.

LEROY A. WILKES

Transactions of Fourth Annual Meeting of American Child Health Association—New York, 1927. 381 pp. Paper. Price, \$3.00.

In these Transactions a clear picture is given of the advance made in the promotion of child health in the last few years by federal and state health and education departments, national organizations, and community groups.

One section of the Transactions is entitled "The Medical School and Child Health. Experience with courses in Preventive Pediatrics and Plans for Future Development," with contributions from faculty members of several leading universities, who are eminent in the field of public health and pediatrics. Reprints of this symposium and reprints of a few individual papers in the symposium can be obtained from the A. C. H. A., 370 Seventh Ave., New York, N. Y.

Another feature of the Transactions

is a series of charts visualizing the progress made in child health in two decades. These charts offer interesting study and at a nominal price reproductions can be obtained in chart and slide form.

Outlines in Health Education for Women—By Gertrude Billhuber, D.P.H. and Isabelle Post, B.S. New York: Barnes & Co., 1927. 192 pp. Price, \$2.00.

This book, designed particularly for use in teaching hygiene to college freshman women, consists of thirty-four outlines to cover a college course with periods twice a week. These outlines develop two major lines of interest: first, health promotion; second, disease prevention and control. The material is authoritative, clearly and practically presented, and freely illustrated. I. L. M.

Tierphysiologischen Uebungen—By Dr. Paul Krüger. Berlin: Verlag von Gebrüder Borntraeger, 1926. xxxv+518 pp. (180 figs.) Price, 30 Marks.

The fundamental values of the dynamic aspects of animal biology are well illustrated in this handbook for the experimental study of the vital processes and functions of the animal body. It is not a human physiology, although there is constant reference to human processes and functions. The method is a comparative one only in so far as it is necessary or significant to bring in modifications of fundamental processes. The aim of the author is very clearly to present as broad a view as possible of vital activities, and he uses the most available material or subject to illustrate each in turn. The treatment is physico-chemical in the main. Less attention than in most treatises is given to reproduction and to muscle-nerve physiology. Experimental morphogenesis is hardly mentioned.

The text is well illustrated and skillfully set up in differential typography

in condensed, terse, carefully subdivided sections. The treatment is well adapted both for laboratory use and for ready reference as a source book for the latest information on the physical and chemical processes in living substances and for the experimental methods of testing physiological processes of the simpler and more fundamental types. Every biologist should have the book at hand. It has three full indices and an exceptionally complete analytical table of contents.

C. A. KOFOID

Leitfaden zu Tierphysiologischen Uebungen—By Dr. Paul Krüger. Berlin: Gebrüder Borntraeger, 1927. 92 pp., (29 figs.) Price, 3 Marks.

This laboratory guide is intended to accompany the author's *Tierphysiologische Uebungen*. It contains brief and exact directions for the experiments in the physico-chemical foundations of biology, the substrate of vital phenomena and the widely varied phenomena themselves. All biologists will find this booklet useful as a reference work on many biological tests and a source for many suggestive experiments illustrating important principles. C. A. KOFOID

The Medical Department of the Army—By James A. Tobey. Baltimore: Johns Hopkins Press, 1927. 161 pp. Price, \$1.50.

The Institute for Government Research, a nonpolitical and extra-governmental association of citizens interested in correct administration of our body politic, has recently published its forty-fifth monograph on the operations of various administrative agencies of the United States.

This monograph, which was prepared for the Institute by James A. Tobey, recites in brief the history, activities and practical organization of the Medical Department of the Army.

The foreword of the booklet contains this statement: "The monographs will serve the double purpose of furnishing an essential tool for efficient legislation, administration and popular control, and of laying the basis for critical and constructive work on the part of those upon whom responsibility for such work primarily rests." The current monograph adequately and competently fulfils this purpose.

The history depicts the gradual up-building, from fragmentary beginnings in 1775, of a great agency of usefulness and mercy. The story is well told, although only the salient facts can be recounted in a work of such limited scope.

The manifold and diverse activities required of the Army Medical Department could not possibly be appreciated by anyone, except by long actual experience or through the medium of such a monograph. Therefore this book will be valuable to all interested in the subject. It will prove useful to medical officers of the army, for it constitutes a comprehensive survey in a convenient form.

The outline of organization affords a broad view of the operations of the department. Divided as it is into Medical, Dental, Veterinary, Administrative and Nurse Corps, with a large force of enlisted and civilian personnel, its functions cover wide fields of endeavor. Its numerous hospitals, dispensaries for treatment and laboratories for diagnosis and research; its schools for basic and post-graduate instruction; the necessity for the maintenance of elaborate records, for the procurement of the thousands of items of supply, for the prevention of disease and for the development of plans against possible emergencies (including immediate aid in public disasters); its great museum and greater library—all these and more require a personnel trained in multifarious ways, of which the monograph presents a clear and accurate picture.

F. R. KEEFER

Health Behavior—*Thomas D. Wood, M.D., Professor of Health Education at Teachers College, Columbia Univ., and Marion Olive Lerrigo, Ph.D., Staff Associate American Child Health Association. Bloomington, Ill.: Public School Publishing Co., 1927. 150 pp. Price, \$2.00.*

Here is a book which will prove of definite value and usefulness in the preparation of a course of study in health education. Teachers and supervisors of health education will find it a valuable reference if they are working in communities which have not developed a detailed health education outline. Health officers will find it of value in presenting a picture of the desirable scope of health education at each age level.

The book consists of six scales each presenting the health habits, attitudes and knowledge which should be acquired by the individual at a particular age level. Scale one presents the habits, attitudes and knowledge which should be acquired by the child before entering kindergarten; scale two by the end of grade 3; scale three by the end of grade 6; scale four by the end of grade 9; scale five by the end of grade 12; scale six those appropriate for adults. These scales have been prepared by accumulating, from literature and public health experience, a complete list of the health problems which confront us and the habits, attitudes and knowledge necessary to solve these problems. From this complete list, the objectives which may reasonably be reached at the various age levels have been determined. The basis of progression recognizes: (1) the needs of the individual, (2) his increasing responsibility, and (3) his interest in an increasingly wider community. Each scale separates the new or changed objectives from those which appear in earlier scales, and it treats separately the habits and skills, the attitudes and the knowledge.

The work is well done and the book is attractively made. It is, of course, a statement of objectives for the teacher and not a textbook for the child. It is not a grade by grade program but rather it groups together objectives for three or more years in each scale. While there might be points of minor difference, there would be essential and general agreement among health education experts upon the soundness of the material.

C. E. TURNER

Feeding Your Baby. Diet for the Child During the First Six Years.

Out of Babyhood Into Childhood. A Health Talk to Parents of Children from Two to Six.

Tuberculosis.

Published by the Metropolitan Life Insurance Company.

These booklets are based on authoritative facts. They can be obtained by writing to the Welfare Education Division, Metropolitan Life Insurance Company, 1 Madison Avenue, New York, N. Y.

After the Rain—*By Grace T. Hallock. New York: Cleanliness Institute. 1927. 96 pp.*

In her usual attractive manner Miss Hallock narrates the cleanliness customs of children in France, Japan, Italy, England, Poland, Finland, Africa and Holland. The book offers material for the story teller at home or in the children's library, and for the primary teachers. It is unfortunate that the illustrations are not comparable with the art displayed in the telling of the story. This book can be obtained by writing to the School Department, Cleanliness Institute, 45 East 17th Street, New York, N. Y.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

England and Wales—The 1926 report of the Chief Medical Officer is a volume of considerable interest to public health administrators. The report contains 281 pages, including appendices, printed on good soft paper in readable type. Several statistical tables and graphs add to the value of this annual statement, but it is particularly noteworthy to find in an annual health report so much interesting and suggestive descriptive text. A somewhat detailed table of contents occupies 2 pages, making it possible to refer readily to special topics.

The estimated population of England and Wales in 1926 was 39,067,000. The population data are analyzed by age and sex, and the growth of total population is shown in tabular form for previous years beginning with 1871. A birth rate of 17.8 represents a decline of 7.7 per 1,000 since 1920. Infant mortality rates of 70 for 1926, of 76 for 1921–25 and of 149 for 1871–1880 are recorded. Diseases of the heart and cancer were the leading causes of death with rates of 142 and 117 respectively. The statistical tables are worthy of careful study and may be used as models by those preparing annual reports. Data are presented to show that by sickness and invalidity, there was lost to the nation in the year, among the insured population only, and excluding the loss due to sickness for which sickness or disablement benefit is not payable, a total of 28¼ million weeks' work, the equivalent of 12 months' work of upwards of 540,000 persons.

The figures relating to smallpox for the last 10 years show an increase in the number of cases and a decline in the number of deaths, with a case fatality

rate in 1926 of 0.15 per cent (10,141 cases). Isolated outbreaks of the severe type, however, still continue to occur. A statistical study of the recent history of diphtheria in London suggests that the apparent decline in the fatality of this disease may be due, in part, to greater care in the notification of mild or merely suspicious cases.

A careful analysis of maternal mortality shows a rate of 4.12 per 1,000 births registered, with 1.02 deaths of women not classed to pregnancy and child-bearing but returned as associated therewith. "Antenatal supervision is the true preventive midwifery; unfortunately, its general application is a question of the gradual education of a generation unaccustomed to regard the ailments of pregnancy as potential dangers, or to realize how much can be done to avoid subsequent disaster by intelligent anticipation and preparation. . . . There are now 722 centers at which antenatal work is known to be carried out."

"The progress of a nation's health is a secular movement, that is a passage through the centuries, and founded mainly upon an exclusive regard to the immediate interests and problems of human survival.—We who are the medical or administrative servants of this undertaking must not allow ourselves to become customary or routine in thought, action or outlook."

Hartford, Conn.—The annual reports of the Hartford Board of Health for 1925 and 1926 are published together in a volume of 28 pages. Following a page devoted to the board organization, is the financial statement which indicates total expenses for 1926 of \$161,307 as compared with \$170,371 in 1925, the

reduction being due to lowered isolation hospital costs.

A population of 164,228 in 1926 is noted, with a death rate corrected for residence of 10.57. A death rate of 53 from tuberculosis, all forms, is noteworthy. A birth rate of 20 and an infant mortality rate of 72 are reported. Approximately 50 per cent of the resident births occur in institutions, and 7 per cent of the births are attended by midwives.

The Visiting Nurse Association is employed by the board to carry on the child welfare work with infants and pre-school children. There are 11 stations, 6 of them being in school buildings. The numbers of home visits by the nurses was 35,994 in 1925 and 32,256 in 1926. The number of visits to clinics was 12,771 in 1925 and 16,992 in 1926. The supervision of tuberculosis cases by a department of the Visiting Nurse Association, while financed by the Community Chest, works also in close co-operation with the Board of Health. The Hartford Dispensary operates two clinics for the examination of adult tuberculosis cases, and a third clinic for children is maintained at Mitchell House—the State Tuberculosis Commission furnishing a physician, the Visiting Nurse Association, the nursing assistance, and the Board of Health, the maintenance charge.

Richmond County, N. C.—This county of 35,000 people has a board of health of 5 members and a staff consisting of a medical health officer, a nurse, and a stenographer-clerk. The report for 1926 indicates that this is a progressive agricultural and manufacturing center where cotton and peaches are grown extensively, although there is a diversification of farm products.

The county health department is maintained jointly by the state and county, the total appropriations amounting to \$8,100. A condensed resume of

1926 gives the cost equivalent valuation system in vogue in North Carolina. It is calculated that during the year, \$7,263.75 was expended; that the total cost equivalents, in services rendered, produced \$17,523.57; giving the earning per dollar invested during the year as \$2.41. These services consisted of immunization, medical and nursing visits, infant and maternal hygiene work, laboratory work, and regular health department activities. The program for 1927, outlined on the last page of the report, includes the inoculation of all children from 6 months to 16 years of age with toxin-antitoxin, and Schick tests of all that have been previously inoculated.

League of Nations—The annual report of the health organization for 1926 shows that 3 sessions of the health committee were held during the year. The actual expenditure (in Swiss francs) in 1925 amounted to 1,544,132, and the estimated expenditures for 1926 are only slightly higher than this figure. During the year particular attention was devoted to the reception and dissemination of weekly telegraphic epidemiological intelligence and of information in regard to the movement of infected ships. These reports have proved to be of enormous interest and value in various sections of the world.

Progress is being made in the standardization of morbidity and mortality statistics, and in the revision of the *International List of Causes of Death*. A group of administrative statistical experts have been invited to sit on the Health Committee to consider the latter problem. An impressive list of epidemiological and statistical publications of the Health Organization is contained in this annual report, together with an account of the work of the various Commissions. These Commissions represent a broad scope of interest, including malaria, permanent standards (sera, drugs, tests), sleeping sickness, opium, cancer,

tuberculosis, public health training, and smallpox and vaccination.

Cleveland, O.—The Cleveland 1926 report contains 34 valuable statistical tables, a map showing the health districts and the location of health stations, together with descriptive text. The death rate was 11.07, and the birth rate was 20.4. Over 47 per cent of all births were registered from either maternity hospi-

tals or in the maternity wards of general hospitals. An infant mortality rate of 71.2 is recorded. It is noteworthy that 35,699 visits were made to infant welfare stations. The average attendance per clinic has increased from 12.9 in 1920 to 14.3 in 1926. A plan to provide protection against diphtheria for children under school age through infant welfare stations has been inaugurated.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

The Bacteriophage Again—An involved discussion of the plurivirulence and the complexity of the bacteriophage, from which final conclusions as to the nature of the phenomenon remain unannounced in this, the first part of a lecture.

BRUYNOGHE, R. The Twort-D'Herelle Phenomenon. *J. State Med.*, 35:11 (Nov.), 1927.

Sewage Tank Design—The majority of sewage settling tanks are inefficient. They should be built to obtain an even distribution of flow at both inlet and outlet ends, and about four times as long as wide. Although baffles may be helpful, they are more often detrimental.

CAPEN, C. H., JR. Study of Sewage Settling Tank Design. *Eng. News Rec.*, 99:21 (Nov. 24), 1927.

Dental Hygiene—A British summarization of the causes of dental decay—a chemico-parasitic theory. The fermentation of starches and sugars about the teeth is the alleged cause. Induce children to banish sweets, eat roughage, and "swill" (rinse) the mouth after eating, and all will be well.

COLYER, F. The Prevention of Caries in Children. *J. Roy. San. Inst.*, 48:5 (Nov.), 1927.

Cereal Diets—White rats fed suitable supplementary foods made normal growths when 84 per cent of the calories were obtained from whole grain cereals. The authors conclude that cereals might be used to a much greater extent in human diets than is customary in America.

COWGILL, G. R., et al. Studies on the Effects of Abundant Cereal Intake. *J. A. M. A.*, 89:21 (Nov. 19), 1927.

Comparison of Diphtheria Immunity—Diphtheria and scarlet fever are

much lower in incidence in Rio de Janeiro than in the United States cities, yet the prevalence of immunity to these diseases, as revealed by tests, is higher. The authors interpret this to mean that infection is more common in the former place.

DOULL, J. A., et al. Common Infectious Diseases in Brazil. (and) Results of Schick and Dick Tests in Rio de Janeiro. *J. Prev. Med.*, 1:8 (Nov.), 1927.

The Vitamins—A brief summarization of the present-day knowledge regarding vitamins.

EDWARDS, M. M. The "Little Things" that Nourish Our Body. *Pub. Health Nurse*, 19:11 (Nov.), 1927.

Gelatin in Ice Cream—Samples of gelatin tested bacteriologically indicated that some lots might affect the bacterial count of ice cream made from cream of low bacterial content. But when added to a mix of high bacterial content (especially when the mix is later to be pasteurized), no appreciable difference in the count should result.

FAY, A. C., and OLSON, N. E. The Effect of Gelatin on the Bacterial Content of Ice Cream Mix. *J. Bact.*, 14:5 (Nov.), 1927.

Modified Measles—This is a report of the use of serum from family donors, when convalescent serum is not available, to modify measles in young contacts.

FORBES, R. P., and BERRYMAN, G. Modified Measles. *J. A. M. A.*, 89:19 (Nov. 5), 1927.

Food Fads—The dietary commandments of the food faddists are given a scorching going over that reduces them to absurdity. This is an excellent paper to stimulate the sanitarian to find out what is really known about nutrition.

HARDING, T. S. Common Food Fallacies. *Scientific Monthly*, (Nov.) 1927.

Tularaemia in Ticks and Bedbugs—A description of the microscopic changes in ticks and bedbugs infected with tularaemia. The epithelial cells of the gut were found swollen and packed with organisms. Organisms could not certainly be identified in salivary glands and a number of other organisms.

FRANCIS, EDWARD. Microscopic Changes of Tularaemia in the Tick *Dermacentor andersoni* and the Bedbug *Cimex lectularius*. Pub. Health Rep., 42:45 (Nov.), 1927.

Hookworm Prevention—Whole-sale treatment for hookworm infestation without sanitation to prevent its continuance resulted in reinfestation in one year of considerable proportions, indicating that in three years the infestation would have reached its previous level.

HILL, R. B. Hookworm Infestation in an Unsanitated District After an Intensive Treatment Campaign. J. Prev. Med., 1:8 (Nov.), 1927.

Activated Sludge Sewage Disposal Plant—Experience in operating the Essen sewage disposal plant indicated the value of adding water heated to 70–80° F. directly to the sludge at the bottom of the digestion tank during cold weather in order to stimulate bacterial action.

IMHOFF, K. Operating Results of the Essen Activated-Sludge Plant. Eng. News-Rec., 90:20 (Nov. 17), 1927.

Syphilis Precipitation Tests—The “pros” of the Kahn precipitation test for syphilis—including the claims of marked specificity, sensitiveness, simplicity, and freedom from error—are presented again by Dr. Kahn. Some of the “cons” are suggested by the discussers of the paper.

KAHN, R. L. Five Years Application of the Kahn Test. J. A. M. A., 89:22 (Nov.), 1927.

Public Health Nursing—The nursing program of the New York State Department of Health is interestingly told in this brief paper. An excellent statewide nursing scheme.

KUHLMAN, M. S. New York State Public Health Nursing. Nation's Health, 9:11 (Nov. 15), 1927.

Studying Juvenile Delinquents—This discussion of the procedure for studying delinquent children will be of interest to all health officials who have any social problems to face—and this should include all officials except, perhaps, plumbing inspectors.

McIVER, J. The Juvenile Delinquent. J. A. M. A., 89:19 (Nov. 5), 1927.

Posture Studies—A correlation is shown between defective posture and pathologic conditions of the female genital organs. This is another reason for including correct posture among the rules of hygiene.

MILLER, N. F. Posture Studies in Gynecology. J. A. M. A., 89:21 (Nov. 19), 1927.

Do Adults Contract Tuberculosis?—When one of the consorts died of tuberculosis the mate was found to be infected in half the cases. The author concludes that with mass infections and lowered resistance adult infection is frequent.

MINNIG, ARNOLD. Conjugal Tuberculosis. J. A. M. A., 89:21 (Nov. 19), 1927.

What to Eat—The keynote of a successful diet is variety—always including milk and green vegetables. Good material presented in a usable form for the sanitarian who is trying to educate.

NEWMAN, SIR GEORGE. The Relation of Food to Health. Better Health (British), 1:2 (Nov.), 1927.

Industrial Mortality—A study of available statistics indicates that tuberculosis is declining as a cause of death of workers, and that it is superseded by cardiac conditions.

PEDLEY, F. G. The Trend of Occupational Mortality in the United States. J. Indust. Hyg., 9:11 (Nov.), 1927.

Eugenic Sterilization—Another paper of a series dealing with the sterilization of defectives; this paper shows

the increase of first admission sterilizations, particularly single women. It should be done early to prevent the birth of defective children.

POPENOE, PAUL. Eugenic Sterilization in California. *J. Soc. Hyg.*, 8:8 (Nov.), 1927.

Sex Differences in Tuberculosis—More females than males die of tuberculosis during the ages 5-24 (maximum 10-14). Probably the causes are biological; the reasoning by which this conclusion is reached is interestingly presented.

PUTNAM, PERSIS. Sex Differences in Pulmonary Tuberculosis. *Am. J. Hyg.*, 7:6 (Nov.), 1927.

Trends in Typhoid Mortality—The accelerated trend of the typhoid fever decline beginning during the latter part of the 19th century to date. The present-day importance of carriers is discussed.

PUTNAM, PERSIS. The Trend of Typhoid Fever Mortality in the United States. *Ibid.*

Maternal Transmission of Hypersensitiveness—The first papers of this series review the findings of others in studies of the transmission of hypersensitiveness from mother to offspring through the placenta and through colostrum and milk. The last papers report studies of the guinea pig which support the hypothesis that human infants manifesting an allergic state have been sensitized in the uterus of the mother.

RATNER, BRET, et al. Transmission of Protein Hypersensitiveness from Mother to Offspring. *J. Immunol.*, 14:5 (Nov.), 1927.

Testing for Carbon Monoxide—A report on the use of the Sayres-Yant method for the determination of carbon monoxide in garages, and a description of the apparatus used.

SALLS, C. M. Carbon Monoxide Tests in Commercial Garages and Automobile Repair Shops. *Ind. Hyg. Bull.* (N. Y. State Dept. of Labor), 4:5 (Nov.), 1927.

Measles Management—An interesting description of the care of measles cases in cubicles. The nursing technic which prevents cross infections is described.

SPENCER, H. J. The Management of Measles in Hospital and Home. *J. A. M. A.*, 89:20 (Nov. 12), 1927.

Radio Health Talks—An attempt to evaluate a series of health talks given from Syracuse. A questionnaire was broadcast and a prize offered for the best answer. Fifty-five replies were received, from which it is estimated that 5500 people listened to the talks.

STONE, J. G. Radio Health Education Talks and Their Results. *Nation's Health*, 9:11 (Nov.), 1927.

Child Welfare—This is a brief discussion of the infant welfare program adopted by the City of Winnipeg. Nothing new.

TUSTIN, P. B. Child Welfare Work in Winnipeg, Canada. *J. Roy. San. Inst.*, 48:5 (Nov.), 1927.

Health Improvement vs. Disease Prevention—An interestingly presented suggestion that health measures may be of immediate benefit to the individual yet react unfavorably upon public health in the long run. This paper should be reprinted in an American publication so that all might read the author's plea for health official participation in all social activities leading to the *improvement of health* as well as disease prevention.

WHEATLEY, J. Relative Values in Health Work. *Pub. Health*, 51:2 (Nov.), 1927.

Mental Hygiene Defined—The inclusiveness of the mental hygiene field, the need for expertly trained leaders and workers, and the possibilities are considered.

WILLIAMS, F. E. Mental Hygiene: An Attempt at a Definition. *Pub. Health Nurse*, 19:11 (Nov.), 1927.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D.P.H.

Epidemiology of Diphtheria—Dr. James A. Doull of Johns Hopkins University presents an outline of the epidemiology of diphtheria in the *Nations Health* for November, 1927. He summarizes his discussion with the following:

1. With rare exceptions the sources of infection in diphtheria are entirely human, namely, cases and carriers.

2. The ordinary mode of infection is directly from person to person.

3. Children are more liable to attack than adults because the latter are more commonly immune.

4. The lower prevalence of the disease in the tropics is due either to a higher degree of natural resistance possessed by the inhabitants or to the bacillus losses in virulence in the warm countries.

5. The lower rates in rural than in urban areas may be explained by less opportunity for contact in the former and a consequently lower infection rate.

As methods of prevention the author stresses: (1) the need of active immunization, (2) isolation, and (3) specific treatment as early as possible.

Cancer Division in Detroit—The *Bulletin* of the Wayne County Medical Society for November 29, 1927, contains the first preliminary report of the Cancer Division of the Detroit Department of Health, which division was established 6 months ago.

During the first 4 months' operation of the newly created division there was a total of 307 deaths from cancer. Of this number 85 occurred from cancer of the stomach. Early and radical operation is the only possible cure for stomach cancer. Of the first 50 deaths, 11 were operated upon, and in four instances an exploration was made. Cases of stomach

cancer when discovered are often too far advanced for surgical interference. The report estimates that somewhere between 40 and 50 per cent of stomach cancer can be recognized soon enough, and are in proper location for radical removal. This is far from the hopelessness which we feel today, but it will only be realized when all indigestions, especially in middle life, are carefully investigated with the X-ray, and operations undertaken without delay if suspicion of cancer exists.

Approximately one-third of the deaths studied in this report were operated upon. Breast cancers were operated upon with the greatest frequency.

The Cancer Division of the Detroit Department of Health is under the direction of Dr. Harry C. Saltzstein, who has medical and nursing assistance. It is now engaged in surveying deaths from cancer, but plans to extend its studies to cases. The program of the department includes stimulating attendance at cancer clinics for early diagnosis, the establishment of a suitable number of hospital beds for early and advanced cases; the education of the public through pamphlets, newspaper articles, and lectures; and the instruction of practicing physicians through clinics and lectures.

League of Nations Epidemiological Report—The *Fourth Epidemiological Report of the Health Section of the League of Nations* for the year 1926 has just appeared. This fourth report is presented in a different form from that of the previous reports. The tables were formerly arranged so as to show each country separately, but now all information is grouped according to disease.

Information on the prevalence of notifiable diseases is now received by the Health Section from practically all countries where such information is collected. The report contains a general view of the prevalence of the infectious diseases throughout the world, together with tables of general mortality, birth rates, infant mortality, and deaths from certain specified causes in large towns.

In discussing the general decline in the diphtheria death rate credit is given to toxin-antitoxin immunization, but mention is also made of the fact that the decrease may be at least partly due to the diminished proportion of children in the population due to the falling birth rate. In the United States the decrease, which had been about 24,000 cases a year between 1922 and 1925, diminished to only 3000 from 1925 to 1926. It is suggested that the reason may be that a new natural rise of the incidence is due, but is nearly checked by the preventive measures.

Scarlet fever is rare in tropical and sub-tropical countries. In Egypt, for example, there were only 6 deaths from scarlet fever in 1926, compared with 617 from diphtheria, and 9149 from measles. Scarlet fever is fairly prevalent in Northern China, but rare in the South. It occurs in Chosen without being very common; it is more common among the Japanese than among Koreans. Scarlet fever has spread steadily in Japan in recent years, but is of common occurrence only in the large towns.

Influenza Epidemic of 1918—The *Journal of the American Medical Association* (November 5, 12, 19, 1927) has been publishing a series of articles dealing with the influenza epidemic of 1918, by Professor Edwin O. Jordan. Professor Jordan, after discussing the incidence of influenza, deals in greater detail with some of the specific control methods em-

ployed throughout the world. Regarding isolation and quarantine he states:

It is quite safe to assert that perfect isolation of an individual or group during an influenza epidemic constitutes a complete protection against the disease. Indeed, it is possible to go further and to maintain that where, as in most cases, it is not practicable to avoid outside human contact altogether, reduction of such contact to a necessary minimum confers some degree of protection, although naturally this is never absolute.

With regard to the closure of schools, Jordan concludes that in large communities little if anything is to be gained by such closure. In smaller towns and in rural sections where general group contacts are not very numerous, restrictive measures may possibly be of service in diminishing the spread of infection. He states with respect to the use of face masks:

The conclusion seems warranted that those attending or examining influenza patients may obtain some measure of protection by wearing properly constructed face masks and eye goggles. On the other hand, the practical difficulties in the way of mask wearing by the general public seem insuperable and render this measure one for individual rather than general prophylaxis.

A rather complete resume of the use of vaccines for prophylactic purposes in civil and military life constitutes a portion of the third article:

Protection against influenza by vaccine inoculation is evidently a broken reed on which to lean. It is not surprising that this is so, since the nature of the causal organism of influenza is still in question. It is disappointing that inoculation with *Bacterium pneumosintes* has not as yet given unmistakable evidence of protective effect; more experiments with this organism should be made. Whether any protection against complications and the secondary infections with pneumococci and other organisms that follow in the wake of influenza can be imparted is uncertain, but deserves further study. Finally, the fact that an attack of influenza confers no such definite and durable immunity as an attack of typhoid or smallpox makes all attempts at this time to produce immunity by inoculation seem distinctly unpromising.

LABORATORY

C. C. YOUNG

THE BUCK PLATE COLONY COUNTER

T. C. BUCK, JR.

Bureau of Bacteriology, City Health Department, Baltimore, Md.

PLATE counting of bacterial colonies in milk, water, ice cream, soft drinks and canned goods has long required an apparatus or method by which more accurate counts can be obtained. Observations from a dozen laboratories have pointed out as many different methods for making such counts.

Correlations of counts from the same plate, within the limits of personal error, could hardly be expected from such varied methods unless the colonies were large enough to be counted with the naked eye or with slight magnification.

Certain bacteriologists engaged in public health work, as well as those in the commercial field, have a tendency to overlook the smaller colonies sometimes present. This may be due to lack of proper equipment such as magnification and illumination. However, not to observe the so-called pin point, transparent and opalescent colonies is to overlook an undesirable condition of milk, water or food. There have been numerous isolations of pin point colonies which have proved to be streptococci, and these have been traced directly to the infected cow with mastitis.

REVIEW OF LITERATURE

Stewart (1906)¹ designed a counting chamber which has been extensively used throughout the country. This counter proved of great value in counting the larger colonies in the milk flora.

Buck and Swenarton (1924)² designed a counter with special attention to pin point colony counting. This counter had

many advantages, as it provided a direct and indirect source of light upon the colonies, agar bubbles, and debris between which it is at times very hard to distinguish.

A recent article by A. C. Fay (1927)³ points out the danger of pin point colonies being overlooked in plate counting, which tends to minimize the value of one of the most widely used procedures of milk control. Undesirable sanitary conditions of the milk due to their presence may also escape attention. He has covered the literature on this subject so thoroughly that repetition seems useless.

OBSERVATIONS

In 1923 the non-correlation of milk and ice cream counts was so marked that it caused no little concern in the laboratory. Counts and recounts were made with great variations. Recounts of the same plate by a number of different workers differed widely. The plates selected for these observations were those containing the smallest colonies, which were soon termed the common pin points.

The laboratory was then using for a colony counter the simple ruled plate (Jeffer) and a hand lens with no artificial light. Therefore on a bright, sunshiny day one counted more colonies than on a dark, cloudy one. Artificial light was then supplied with the development of the present counter.

DESCRIPTION

The counter is now supplied with artificial light from an elongated, 25-watt

ground glass bulb (represented by (J) in Figure I), which is incased in a ducoed metal frame. The case is so constructed that all outside light is excluded, and it is provided with two doors for this purpose. The tray holds, first, a dark blue glass plate (E). This permits indirect light rays to come from beneath, giving a translucent light which is much desired in counting transparent and opalescent colonies. Upon the blue plate is placed the ruled Jeffer plate (D), and then the protective glass plate (C). The latter plate provides a depth which enables one to see through the Petri dish before the lines of the Jeffer plate are reached, and should be replaced at intervals to avoid the accumulating scratches. Inside the casing, there are two rotating mirrors, (F) and (G), and also two stationary ones. (I) and (H).

These provide the amount of uniform light desired both above and below the plates.

The entire counting field is visible (instead of only a portion), as the counter is equipped with a specially designed $3\frac{1}{2}$ times lens, (A), as specified in *Standard Methods* of the American Public Health Association.

By reason of the brilliant illumination and special lens set in a stationary position, the operator can readily distinguish pin point, transparent and opalescent colonies, and will not confuse them with agar precipitates, bubbles, or debris.

The counting may be done with much greater speed, far more accurately, with less tedium and much less eye strain than with other counters.

FIGURE I.—COLONY COUNTER

A—Lens
B—Petri dish in proper position with top removed
C—Protective glass plate
D—Jeffer plate
E—Dark blue glass plate
F and G—Rotating mirrors

H and I—Stationary mirrors
J—Elongated electric bulb.
K—Ducoed reflector
L and M—Light guards
N and O—Directed light rays

The plates to be counted are usually arranged on the left hand side. The top is removed; the plate is placed in the counter, and then counted. The top is then replaced on the right hand side. The Petri dishes are placed in a convenient pile or basket. Inverted plates placed in the counter are not desirable, as the scratches on the Petri dish will obliterate the small colonies and do not allow the proper magnification.

EXPERIMENTAL WORK

A comparison between the Buck counter and other prevailing counters was established from nearly 1,000 plate counts. These plates were selected and placed in three groups, namely, A, B and C, all counts being made according to *Standard Methods* of the A. P. H. A.

Group A—This consisted of about 360 plates containing pin point colonies, agar precipitates and debris. There existed no correlation between the different methods, this counter registering from 10 per cent to 250 per cent more colonies than the counts by the ruled glass hand lens method, the Stewart, or the Buck-Swenarton counter.

On several plates by three different workers there were declared no colonies by the hand lens method and the Stewart counter. The present counter registered from 60 to 240 colonies in the several plates. On recount of these plates by five different technicians, all using the new counter, a very high percentage correlated.

Group B—This consisted of 340 plates containing large and small colonies of opalescent or transparent colon bacilli and common udder cocci. Of the 340 counts, 60 per cent was higher by the new counter. On 30 per cent of the counts the other methods showed slightly higher counts, but it was found that they included quantities of precipitates and debris. This result was obtained by circling the colony or debris in question with a pencil, and their identity was then established by the compound microscope.

Group C—About 300 plates were selected for the larger colonies of the common lactic acid type. All methods gave approximately the same results.

From Groups B and C, about 100 Breed counts were made and compared to the results obtained by the Buck

counter and the ruled glass and hand lens. The Buck counter showed that 86 per cent was nearer to the approximate

Colony Counter—Front View.

plate count computed from the Breed count, of which only 6 per cent was approximately the same. The ruled glass and hand lens method gave 8 per cent nearer the approximate plate count computed from the Breed count. These counts were selected for comparison in the hope of securing something near the maximum differences occurring when the very small or pin point colonies were present. Seventy per cent of the Breed counts showed numerous cocci in short chains or in small groups of 4 to 10 cells. These were designated as probable thermotolerant streptococci. Better correlation between the Breed and plate counts was obtained with the new counter.

OBSERVATIONS OF PIN POINT COLONIES

Group I—Pin point colonies, or ones closely resembling them, may be found after repeated pasteurizations of raw milk. Sixty-one samples of raw milk that were selected were pasteurized at 63° C. for 30 minutes, cooled to 8° C., and held at this temperature from 12 to 14 hours. They were then repasteurized and cooled three times, plated and counted after

each cooling. Of the 61 samples 48 per cent produced these small or pin point like colonies usually after the third pasteurization.*

Group II—Fifteen samples of milk from cows suffering with mastitis were plated; 7 of these proved to contain typical pin point colonies. These were about 0.175 m.m. in the longest dimension. The Breed counts showed many short chain streptococci. Isolations and cultures of these were also typical of the streptococci group.

Group III—From more than 500 plate cultures 10 strains of these thermophilic colonies were successfully isolated. These colonies presented themselves in a ratio of 10 to 1 over the other groups. Ten strains were successfully isolated, 2 of which were traced directly to cows with mastitis. These colonies were much smaller than those of the other groups. The Breed counts were higher and these organisms resembled those of Group II. In some cases the chain-like formation was shorter, presenting small chains of from 8 to 10 cells. The plate counts from this group were found to correlate through the three dilutions, namely, 1 to 100, 1 to 1,000, and 1 to 10,000. The approximate plate counts ranged from 150,000 to 5,000,000. These colonies under the lower power microscope presented a small, round, irregular, somewhat transparent appearance, measuring about 140 m.m. in the longest dimension. They were non-motile, Gram positive cocci, somewhat smaller than the short-chained streptococci. Streaked on blood agar a very fine, transparent growth appears after 48 hours, and a slight laking of the red cells

takes place. The thermal death range is somewhat above 80° C. for 10 minutes. They are heat resisting, hemolytic streptococci, and no doubt may be quite troublesome to both the dairies and health departments.

CONCLUSIONS

No. 1. The new counter which has been described provides for a more accurate count of bacteria by the plate count than with any other colony counter in general or accepted use.

No. 2. Pin point colonies are more readily detected and counted than when using other methods.

No. 3. The very minute, or pin point, colonies studied consisted of both the short and long chain types of streptococci which are associated with bovine mastitis.

No. 4. The method of lighting renders it easy to distinguish between fine colonies and bubbles, flakes, or other forms of debris.

No. 5. This counter provides excellent illumination, minimizes eye strain, and keeps the whole Jeffer plate under constant magnification.

* These experiments were conducted on milk during the spring of the year from dairies troubled with pin point colonies, though none of these samples showed pin point colonies in the raw milk.

VITAL STATISTICS

LOUIS I. DUBLIN, PH.D.

Tuberculosis among Infants in New York City—Recent studies and observations indicate that many infants exposed to tuberculosis develop such a high resistance to the disease that the proportion of babies dying from it is very small in comparison with those infected. Only 1.3 per cent of infants attending baby health stations reacted positively to tuberculin tests, and among those attending clinics the percentage was 4.5. This total of 3 per cent of positive reactions in these two groups is probably a more correct estimate of the incidence of tuberculous infection among infants under 2 years in New York City than the 10 to 12 per cent estimate usually accepted.

The incidence of infection varies with age, reaching its maximum between 1 and 2 years. But the percentage of deaths among infants exposed before they are 12 months of age was 50 per cent, and only 26 per cent for those exposed between 1 and 2 years. The tuberculin reactions ranged from 11.4 to 12.7 for Negro, Jewish, American and Italian babies, while for the Irish it was as high as 15.6. Although the number of positive reactions among Jewish babies was about 1 per cent higher than for Negroes, only 1.2 per cent of deaths occurred among Jewish babies, while the percentage of deaths among Negroes, 5.9, was exceeded only by the Irish, with a percentage of 7.8.

When the later condition of 405 positive infants was studied, 209, or 51.7 per cent, were found to be dead. Tuberculosis was the cause of death in 57 per cent of these cases, broncho-pneumonia caused 14 per cent and marasmus another 14 per cent of these deaths. Forty-

one per cent of those infected under 6 months were still living, 46 per cent of those infected between 6 and 12 months and 56 per cent of those infected between 12 and 24 months were also living.

No history of contact could be traced in 55 per cent of 341 infected infants but in 45 per cent it was definitely traced to tuberculosis in the family, lodgers, visiting friends or near neighbors. Of 149 infants thus exposed, 44 per cent were alive, while the majority of the deaths were due to tuberculosis. Of 187 with no history of contact, only 18 per cent were ill with tuberculosis, 82 per cent were infected but had no clinical manifestations, and only 33 per cent of the deaths were due to tuberculosis. Sixty-five per cent of 40 infants remaining at home in contact with diseased mothers died of tuberculosis while of 37 boarded out, only 2 per cent died of the disease.—M. Alice Asserson, *Am. Rev. Tuberc.*, 16:359-378 (Oct.), 1927.

Public Health in Switzerland, 1926—The federal service of public hygiene reports a large decrease in the number of cases of diphtheria, from 7,702 in 1920 to 2,617 in 1925 and 1,930 in 1926. The epidemic of smallpox, which began in 1921 and lasted about 5 years, was without a parallel in the history of smallpox in Switzerland since Jenner's discovery. In spite of the opposition to vaccination in certain parts of the country, measures were adopted which resulted in the vaccination of the majority of the population. Epidemic encephalitis and cerebrospinal meningitis were less prevalent in 1926. Puerperal fever also decreased from 30 cases in 1925 to 26 in 1926.

The number of cases of measles has increased, and in some localities the disease appears to have assumed a severer character than in former years. Scarlet fever increased from 1,980 cases in 1925 to 2,387 in 1926, especially in Berne where there were 757 cases. Poliomyelitis increased slightly from 93 cases in 1925 to 96 in 1926. An epidemic of typhoid fever in an insane hospital caused an increase from 259 cases in 1924 and 300 in 1925 to 328 in 1926. The number of cases of trachoma increased to 21 in 1926 as compared with 16 in 1925. In most instances the patients were foreigners but the authorities are making vigorous attempts to control the disease.

Toward the end of 1926, Switzerland was invaded by an epidemic of influenza which lasted for 2 or 3 months, and caused much uneasiness. During the last 2 weeks of the year 15,013 cases were reported which probably represented only a portion of the actual number prevalent.—*J. A. M. A.* 89:1796 (Nov. 19), 1927.

Cancer in Mexico—At the present time cancer is only about one-half to two-thirds as common in Mexico as in the United States, but it seems to be slowly increasing. The death rate from cancer in the whole country, although not accurately calculated, probably ranges from about 50 to 60 per 100,000 population.

Cancer is relatively common in the large cities but does not seem to be as prevalent as in the large cities of this country. The cancer death rate in Mexico City from 1922 to 1925 was about 60 while in Guadalajara, the next largest city, it was only 16 per 100,000 population. This extremely low figure suggests that there must be inaccuracy in diagnosis or in the reporting of deaths by specific causes. Vera Cruz and Merida both had rates of approximately 80 in 1925. In Oaxaca the rate was 40 and in Salina Cruz from 40 to 50. In spite of deficiencies

in reporting and inaccuracies in diagnosis, however, the conclusion is justified that cancer is relatively rare in both the native Indian and mixed-blood populations.

Cancer of the buccal cavity is more common among women than would be expected, possibly because of the great extent of the smoking habit among Mexican women. Cancers of the stomach, of relatively rare incidence, and of the liver are of about equal frequency in the sexes but cancer of the rectum and intestines is more common among women. There is a very high incidence of cancer of the female genital organs and especially of the cervix, probably because of the high fecundity of the Mexican women, but cancer of the breast is relatively infrequent. Cancer of the skin is found to an equal degree in both sexes. In general, cancer is decidedly more frequent among women than among men.

About 1 per cent of all deaths in Mexico were reported as due to cancer as compared with 5 to 10 per cent in most civilized communities. Cancer seems to occur at a relatively early period of life in Mexico, for the average age at death from cancer for both sexes was 49.8 years, or 52.9 for males and 48.7 for females in the Mexican City Hospital. The average age at death for cancer of the female genital organs was 46.6 years, and 48.9 for cancer of the breast. For both sexes combined the average age at death from cancer of the buccal cavity was 59.4 years, for cancer of the stomach and liver 54.8, for cancer of the rectum and intestines 49.9 years and 48.9 years for cancer of the skin.—Frederick L. Hoffman, *Prudential Press*, Apr. 14, 1927.

Negro Mortality in Chicago—Although Chicago in 1925 had the lowest death rate of any city of more than one million population, only Bombay and Calcutta had a higher rate than that of the negroes in Chicago. The negro death

rate of 22.5 was more than twice that of the white, and the infant mortality rate was 119 as compared with 71 for the white. The negro stillbirth rate was more than twice as great, the death rate from tuberculosis and syphilis was nearly six times as great, and from pneumonia more than three times as large as the white rates.

The death rate from pulmonary tuberculosis among negroes declined considerably between 1918 and 1921 but it has increased steadily since 1921, partly because of the large influx of negroes from the southern rural areas. The death rate from puerperal causes in 1925 was 21.8, more than twice the white rate of 9.4.

The 1920 census showed that 34.9 per cent of negro married women are gainfully employed, but there are only 4 colored day nurseries with provisions for 91 children in the whole South Side. More than one-third of the hospitals throughout the city have some restrictions on the admission of negro patients and there are very few clinics, dispensaries and infant welfare stations in the colored sections. The negroes like the Mexicans, who also have high death rates, live in the most outworn houses in the city and pay higher rents than any other class in the community. Eighty-five per cent of the negroes live in "cold water" apartments with only stoves for heat, and one-third have no toilets in their apartments.—H. L. Harris, Jr., *Social Serv. Rev.*, 1:58-77 (Mar.), 1927.

Cancer in Massachusetts—In 1920-1923 the cancer death rate in Massachusetts, adjusted for age and sex distribution, was the highest of any state in the Union. New York, Rhode Island and Connecticut, all with a high concentration of urban population and many foreign born inhabitants, ranked next in order. A comparison of the adjusted death rates in communities of different densities showed a steady increase from

86.3 in communities with a density of less than 50, to 131.4 in communities with more than 3,000 persons per square mile. This apparent relation between increasing death rates and greater densities, however, is not found among the native born of native parents, and seems to be due to the fact that the percentage of foreign born population increases steadily with the density. The foreign born is an older group than the others and most individuals born in foreign countries have a high death rate from cancer, varying from 84 for those born in Italy to 323 for those from Ireland in Massachusetts 1921-1925.

A small part of the relation between high death rate and greater density may also be due to the fact that there is more accurate diagnosis of cancer in the cities because of better diagnostic facilities.—Herbert L. Lombard and Carl R. Doering. *Proc. Nat. Acad. Sci.*, 13:728-735 (Oct.), 1927.

The After-History of Sanatorium-Treated Patients—The after-history of 384 patients treated in the last half of 1922 in the King George V Sanatorium was traced as far as possible in 1926. Only cases in which the diagnosis of pulmonary tuberculosis was confirmed were included. This study seems to indicate that the age of the patients, records of temperatures and hemorrhages had little value in giving the prognosis of any case of pulmonary tuberculosis.

In 1914 and 1915, 70 per cent of all cases treated in sanatoria were dead within 4 years but only 35 per cent of the 384 patients studied in 1926 had died in the same period. Twenty per cent of them were either doing or were capable of doing full or ordinary work, 9 per cent were in some new occupation, usually a lighter or more suitable one, 24 per cent were unfit to work, 4 per cent were undergoing further institutional treatment and 7 per cent were untraced. Among the 48 cases discharged as quies-

cent 8 per cent had died and 58 per cent were at work of some kind, 32 per cent of the 148 discharged as much improved were dead and only 28 per cent at work, 24 per cent of the 116 early cases discharged as much improved had died and 30 per cent were working, 64 per cent of the late cases discharged as much improved had died and only 19 per cent were able to work. Twenty-one per cent of the 103 cases discharged as fit for full work were dead, 29 per cent at full or ordinary work, and 15 per cent doing lighter work, of the 118 discharged as fit for light work, 36 per cent were dead, 16 per cent doing full or ordinary work, and 8 per cent at more suitable work, 62 per cent of the 99 discharged as unfit for work were dead, 9 were doing full work, and 1 per cent were at more suitable work.

The percentage of deaths varied from 42 per cent of the patients between 16 and 25, to 40 per cent of those over 25 and under 40, and 35 per cent of those over 40. In the first age period 25 per cent were at work of some kind, 28 per cent of the second age group and 25 per cent of the third age group were at work.—C. O. S. Blyth Brooke. *Med. Off.*, 38: 163-165 (Oct. 8), 1927.

The Incidence of Infectious Diseases in Italy in 1926—The *Bollettino delle malattie infettive* contains the official report for the year 1926 on the incidence of infectious diseases, in comparison with the previous year. Almost all infectious diseases show a decrease in the number of cases, over that of 1925. The exceptions are influenza, typhoid and paratyphoid, and pertussis. The principal figures are as follows: measles,

98,155 cases in 1926, as against 164,485 in 1925; scarlet fever, 16,062 cases in 1926 and 16,733 in 1925; typhoid, 35,649 cases in 1926 and 24,264 in 1925; paratyphoid infections, 6,711 cases as against 5,036; influenza, 184,499 cases in 1926 and 64,736 in 1925; diphtheria, 14,923 cases in 1926, as compared with 15,383 in 1925; pertussis, 31,282 cases in contrast with 23,756 for the previous year; epidemic encephalitis, 450, as against 681, and malaria, 220,602 in 1926 and 283,109 in 1925. There were, in addition in 1926, 34 cases of exanthematic typhus, 31 of which developed in Naples, being due to imported food products. There were no cases reported of Asiatic cholera, plague or yellow fever.—*J. A. M. A.* 89:1797 (Nov. 19), 1927.

Heart Disease in the South—The relatively low incidence of acute rheumatic fever and chorea and the large negro population in the South give a different aspect to the problem from that of the East and the North. The study of 915 patients with heart disease in Galveston, Tex., shows that the incidence of heart disease in negroes is 1.8 times as great as in the white race. Impairment of renal function occurred in one-third of all the cases of heart disease.

Of the 915 patients, 47.7 per cent were hypertensive, 19.3 per cent syphilitic, 13.7 per cent arterio-sclerotic, 7.3 per cent rheumatic, 2.3 per cent had angina pectoris, 1.5 per cent showed subacute bacterial endocarditis, 1.3 per cent were thyrotoxic, 0.7 per cent had congenital heart disease.—Charles T. Stone and Francis R. Vanzant. *J. A. M. A.*, 89: 1473-1477 (Oct. 29), 1927.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C.E.

BOARD OF PUBLIC HEALTH ENGINEERS OF OHIO RIVER BASIN

W. L. STEVENSON, FELLOW A. P. H. A.

*Chief Engineer, State Department of Health,
Harrisburg, Pa.*

WHAT is believed to be the first "de-facto" river board in the United States was created by a formal action of the commissioners of the health departments of the States of Pennsylvania, Ohio, West Virginia, Kentucky, New York, Maryland, Indiana, Illinois and Tennessee, at a meeting which they held in Cincinnati on October 18, 1927.

In 1924, the health departments of Pennsylvania, Ohio and West Virginia, entered into an Inter-State Stream Conservation Agreement, which provided for coöperation between these departments for the abatement of pollution in one state harmful to public interests in the adjacent or downstream state.

Under this agreement the Health Departments of Ohio and West Virginia caused to be brought about at by-product coke ovens within their jurisdiction, the installation of works to prevent discharge of phenolic substances affecting water works intakes in Pennsylvania on the Beaver and Monongahela Rivers, which resulted in relief from offensive tastes and odors in those water supplies.

Prior to the making of this agreement, such steps had already been taken by the Pennsylvania by-product coke ovens on the watershed of the Ohio River, with one exception, and through efforts of the Pennsylvania Department of Health, works are about to be installed at that one remaining plant.

Later the Kentucky Department of

Health became a supplemental party to this inter-state agreement because of its evident benefits, as did subsequently, the remaining states as above enumerated.

The commissioners of health, parties to this agreement, in the latter part of 1926, appointed their chief engineers to constitute a board charged with the duty of recommending to the commissioners, policies and *modus operandi* to render the agreement effective.

At the meeting of the commissioners in Cincinnati they adopted the following resolution:

WHEREAS, it is necessary to adopt certain policies and procedures in order effectively and efficiently to carry out the letter and the spirit of coöperation and conscience upon which the Ohio River Interstate Stream Conservation Agreement is founded, therefore be it

RESOLVED, that the following policies and procedures be adopted as part of the said agreement.

1. The chief engineers of the Departments of Health, signators to the Ohio River Interstate Stream Conservation Agreement, shall constitute the "Board of Public Health Engineers of Ohio River Basin" hereinafter referred to as the board.
2. The board shall meet at least annually, during the first week of December and shall recommend, from time to time as may be deemed necessary, to the health commissioners, signators to the agreement, ways and means for effectively and efficiently carrying out the letter and the spirit of the agreement.
3. As adequate protection of public water supplies from damage caused by phenol and other tarry acids discharged into the source

of such supplies requires substantially complete and continuous elimination of the discharge of wastes containing such constituents, or substantially complete and continuous removal of such constituents prior to discharge, therefore the signators of the agreement should institute action promptly to require such elimination or removal by suitable treatment prior to discharge.

4. The signators to the agreement will notify promptly downstream or adjacent signators of unusual events affecting the Ohio River or its tributaries, such as phenol spills, typhoid fever epidemics, etc., in order that suitable measures may be taken by such downstream or adjacent signators to the agreement as are needful to protect the public health.
5. The signators to the agreement, in matters relevant thereto will coordinate present and proposed research, exchange data derived therefrom and exchange ideas on administrative policies for mutual benefit.
6. The signators to the agreement will furnish to downstream or adjacent signators data concerning discharge of sewage or industrial wastes or the treatment thereof in cases where such matters might prejudicially affect such signators in order to obtain thereby the views and judgment of such downstream or adjacent signators.
7. Any signator to the agreement invoking the provisions thereof for abatement of alleged

harmful pollution first shall establish the fact that the cause of the alleged harmful pollution does not exist within its own jurisdiction but does exist within the jurisdiction of the upstream or adjacent state.

8. The signators to the agreement in matters involving mutual concern will arrange for joint inspections of water works, alleged pollution of interstate streams, the alleged effects thereof, the stream involved therein, proposed remedies, and reports thereon whenever deemed necessary.

The commissioners of health parties to the agreement are as follows: Theodore B. Appel, M.D., Secretary of Health, Pennsylvania; John E. Monger, M.D., Director of Health, Ohio; W. T. Henshaw, M.D., Commissioner of Health, West Virginia; A. T. McCormack, M.D., State Health Officer, Kentucky; Matthias Nicoll, Jr., M.D., Commissioner of Health, New York; John S. Fulton, M.D., Director of Health, Maryland; Isaac D. Rawlings, M. D., Director of Public Health, Illinois; Wm. F. King, M.D., State Health Commissioner, Indiana; E. L. Bishop, M.D., Commissioner of Health, Tennessee.

The members of the Board of Engineers are as follows: W. L. Stevenson, Chairman, Pennsylvania; F. H. Waring, Secretary, Ohio; E. S. Tisdale, West Virginia; F. C. Dugan, Kentucky; C. A. Holmquist, New York; Abel Wolman, Maryland; H. F. Ferguson, Illinois; L. S. Finch, Indiana; H. R. Fullerton, Tennessee.

School Ventilation Laws—This very brief paper provides certain basic principles which the New York State Commission on Ventilation have formulated in response to requests for suggestions as to the matter which should be included in school ventilation laws. The requirements for heating and ventilation are essentially the following: (1) The provision of sufficient heating capacity to heat (a) corridors, gymnasiums and shops to 65°; (b) swimming pools and dressing rooms to 75°; (c) all other occupied rooms to 68°; (2) all classrooms shall have at least 15 sq. ft. of floor space per pupil and shall have a system of ventilation capable of avoiding the production of unpleasant odors usually associated with more than 15 parts of carbon dioxide per 10,000, and ca-

pable of functioning without producing chilling drafts. Such ventilation shall be accomplished by either window-gravity or mechanical means or by any other method which will attain the desired result. Ventilation of auditoria, chemical laboratories, shops, etc., shall be obtained preferably by mechanical means; (3) every schoolroom shall be provided with at least one thermometer; (4) an approved system of ventilation shall be maintained in operation whenever school is in session.—Thomas J. Duffield. *J. Am. Soc. Heat. & Vent. Engrs.*, 33:388 (June), 1927. Abstr. Leonard Greenburg.

Food Poisoning by Rats—The matter of food poisoning by rats is still an important problem. Meyer and Matsu-

mura of the California Hooper Foundation for Medical Research found approximately 8 per cent of the rats examined infected with one or two transmissible bacterial diseases, 2 per cent shedding virulent types capable of infecting food and further that 6 per cent near slaughterhouses and retail merchants could do this.

Feces were added to food of kittens and tame rats and four rat-borne diseases were produced—hemorrhagic septicemia, plague, rat typhoid and pseudotuberculosis. The first, being similar to plague, has complicated the campaigns against it, but now that the specific organism has been located and classified, the disease can be definitely diagnosed.

If conditions exist as these observers picture them, it is high time that a very definite program for eradication of the rat be instituted for there are worse conditions than these men found.—Anon. *Hygeia*, 5:14 (June), 1927. Abstr. H. D. Cashmore.

A New Means of Combating Anopheles in Italy: An Account of the Acclimatization and Progress of Gambusia—The author gives a review of the value of indigenous fish as eradicators of mosquito larvae and concludes: "For my part I am perfectly convinced that there do not exist any fishes of our own country (or probably in Southern Europe) which can be employed efficaciously in the antimalaria fight." Then reference is made to the arrival of "some hundreds" of gambusia in 1921 at Madrid, Spain, which had been shipped from the United States (U. S. Fisheries Station, Edenton). The fish were placed in a pond near Madrid and a year later this pond and the communicating streams were "crowded" with gambusia. Two or three hundred were then transferred to Italy, arriving in Rome in 1922. These fish were divided into four lots. They multiplied rapidly and the following April the effects be-

came evident, for "the Lago di Porto which had been swarming with mosquito larvae in previous years, now only rarely presented a specimen."

Gambusia multiplied and invaded canals and other waters. It is reported that they have been liberally distributed over many parts of Italy, and they have been introduced from Italy, directly or indirectly, into Germany, Russia and Jugoslavia. The opinion is expressed that gambusia multiply more rapidly in Italy than in the place of their origin, namely, the United States.

The author says, "After four and three years, respectively, from the time of importation of gambusia into Spain and into Italy we have to thank the United States for the precious gift which they have made us, the value of which we no longer doubt." The conclusions are that complete mosquito control is obtainable, if there is complete control of vegetation. Vertical vegetation leaves to gambusia the possibility of complete destruction. Horizontal vegetation often prevents complete control. The relative degree of control in the presence of such vegetation, however, depends on the number of fish present. In some extensive zones not a drop of petroleum has been used, yet, the mosquitoes have been reduced to a minimum this year (1925), something never before obtained.

A reduction in malaria incidence also is reported. The author concludes: "The results of this initial period warrant, therefore, the affirmation that in gambusia, Italy acquired a new means for the reduction of the larvae of the anopheles." Maximus Sells. *Rendu Du Premier Congres International Du Paludisme*, Rome, 1926. 16 pp. Abstr. S. F. Hildebrand.

Burning Gas from Imhoff Tanks at Decatur, Ill.—Due to the strength and high temperature of the Decatur sewage, bacterial decomposition and putrefaction take place rapidly in the

sewers and in the Imhoff tank, producing large quantities of odorous gases. A collecting arrangement has been provided by means of which about 100,000 cu. ft. of gas per day is now caught, having a heat value of 700 B.T.U. per cu. ft. By burning this gas, the odor nuisance about the treatment plant was immediately reduced. Details are given regarding the composition of the gas under different conditions. William D. Hatfield. *Water Works*, 66:99 (Mar.), 1927. Abstr. D. E. Kepner.

Disposal of Trade Sewage—The writer points out the importance of proper disposal of trade sewage, indicating that this phase of sanitation is becoming more and more necessary. One of the most serious problems in trade waste sewages is the nature and concentration of these wastes. Until recently little has been known of the various chemical and biological activities taking place in trade wastes, but more lately continued study of the different lines of this work has shown that each trade sewage presents an individual problem in itself.

Three general ways of handling trade sewage are: (1) By fine screening, followed by sufficient dilution to prevent undue stream pollution; (2) partial treatment to destroy acid forming bacteria or to so change the trade sewage as to make it equivalent to ordinary domestic sewage thereby permitting it to be run into the municipal sewer system; (3) complete treatment of trade sewage so that the effluent can be wasted into any stream or storm sewer.

The writer devotes some space to pointing out the fact that it is ill advised to force a part-time industry to spend so much on trade sewage treatment as to cause that industry to either abandon its work or to move to another locality.

Study of each particular problem will probably reveal methods of treating wastes which will be economically pos-

sible. For example, a particular sugar beet company experimented with trickling beds of stone for producing a stable effluent. One of the materials used in the beds was crushed granite, the cost for which for a complete plant would have been \$90,000, and another material was cinders, the similar cost for which would have been only \$20,000. If the cinders prove to be as satisfactory as granite and also answer the other requirements there will be saved, approximately, \$70,000. C. H. Currie. *Munic. & County Eng.*, 72:249 (May), 1927.

A Texas Water Supply Enlargement Problem Involving a Dual Distribution System—The question of the advisability of distributing water to a community by a dual system may arise in certain parts of this country, particularly in the southwest where large quantities of water are used for irrigation purposes.

Wichita Falls, Tex., is cited as a city where the relative economy of dual systems will probably have to be considered seriously as the city grows. Lake Wichita, the source of the present water supply, could furnish a satisfactory soft water for domestic purposes in the future provided another source of supply, possibly Lake Kemp, which furnishes water which is saline and very hard, might be utilized for irrigation and fire fighting purposes.

The relative costs on single and dual systems are set forth in the article and following conclusions drawn: (1) Dual systems are more expensive in first cost and in operation than single systems due to duplication of pipe lines, services, pumping plant and accessories; (2) some unusual situation such as the inadequacy of a suitable water supply together with an unusually high cost for an additional supply or excess treatment costs must exist before a dual supply can be economical. N. T. Veatch, Jr. *Proc. Ninth Texas Water Works Short School*,

Jan. 24-29, 1927. Pp. 59-63. Abstr. E. S. Tisdale.

Recent Improvements and Criticisms of Imhoff Tanks—The upper part of the sedimentation chamber should be given the largest surface area because depths of over 6 feet cannot be included in the computation of the detention period. One hour detention period is enough, but longer periods may be desirable, especially when contact aerators will be provided for. The sludge digestion chamber should be as deep as possible but should have a minimum of water surface.

Gas traps should be built in all large Imhoff tank installations. The construction costs are very slight as the already present slant partition walls for the separation of the sedimentation chamber from the sludge digestion chamber serve as gas retainers. The amount of gas is about 8 litres per head per day which can be increased at higher temperature to threefold. Imhoff tanks whose septic chambers have become too small may be provided with secondary sludge digestion tanks into which the half-digested sludge can be pumped. In the meantime the sludge from the secondary tank is allowed to return into the Imhoff tank. In winter there is the additional advantage that the cold separate sludge digestion chamber is heated by the warm Imhoff sludge. Contact aerators (that is to say, submerged structures into which air is supplied from below), have to date proved themselves very economical. The disadvantages of Imhoff tanks as compared with the single story sludge digestion tanks are briefly as follows: Construction is deeper, foaming during the ripening period or later damages the stabilization, and it is impossible to artificially heat the septic chamber. Among the advantages are: the automatic con-

tinuous flow of sludge from sedimentation chambers, the even distribution of fresh sludge into septic chambers, the septic chambers are naturally kept warm by the flowing effluent, the installation of gas traps are cheaper owing to the presence of slanted partitions, the relatively small amount of CO₂ in the gas and the simplicity of operation. Karl Imhoff. *Proc. Ninth Texas Water Works Short School*, Jan. 24-29, 1927, pp. 369-371. Abstr. H. H. Rashid.

Bacterial Efficiency of Mechanical Gravity Filters—The investigation was carried on to determine the bacterial efficiency of filters independent of the other devices usually associated with this type of plant.

The plants studied comprised 14 Paterson gravity type filters, 4 Jewell gravity filters and 6 Mather and Platt type filters, all taking water from the Ganges within a distance of 15 miles. The only variable factor in so far as the raw water was concerned was the bacterial pollution. The water in every case, after a varying dosage of alum, was given a short period of sedimentation. The efficiency of the filters was determined by the *B. coli* removal. The investigation was continued through two years. The summary of results from each of the eight plants studied is given. In general 75 per cent of the samples showed a 90 per cent removal of *B. coli*.

The writer points out that, where chlorination is not depended upon, the preliminary treatment devices should be so designed as to allow for the water to be delivered to the filters with a bacterial content such as to permit the filters to deliver a uniformly satisfactory water. Rao Sahib V. Govinda Raju. *Indian J. M. Research*, 14:707 (Jan.), 1927. Abstr. R. E. Tarbett.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH.D.

The Psychoneurotic Worker—It is quite common that when one undertakes a research for some definite purpose the by-products of this research are as valuable, if not more valuable, than the particular information anticipated. In a study of telegraphists' cramp, made under the auspices of the Industrial Fatigue Research Board of Great Britain, the following claims of interest to industry were made. From an examination of 100 learners the investigators found that it was possible at the age of 16 to differentiate the psychoneurotic workers from the normal. They also found from studying additional groups of workers that approximately 20 per cent possessed personalities which are liable to "nervous breakdown"; and that certain occupations, one of which is telegraphy, tend more than other occupations to help make for an increase of symptoms.—May Smith and Eric Farmer, *A Study of Telegraphists' Cramp, Report No. 43*, Industrial Fatigue Research Board, London, 1927. *Human Factor*, 3:11 (July-Oct.), 1927.

Fifty Years of Legislation on Occupational Diseases in Switzerland—During the last forty or fifty years the principle of occupational risk has been successively adopted by the legislative systems of almost all countries. While this applies to accidents, in most countries no compensation is payable for industrial poisons or infections. The experience of Switzerland, the first country to adopt occupational disease legislation, now covers half a century. Its principle was first applied to the manufacture of matches with white phosphorus and the use of Jacquard looms with lead weights.

An historical survey shows that the schedule method was early adopted, in 1901, 34 disease hazards being listed. In September, 1920, the list was extended to over 100 disease causes, principally poisonous substances. (The article discusses at some length the legal provisions adopted in regard to occupational diseases in Switzerland.)—Dr. Werner Lauber, *Internat. Labour Rev.*, 16:472-486 (Oct.), 1927.

Carbon Monoxide Tests in Commercial Garages and Automobile Repair Shops—The Sayers-Yant method of estimating very small quantities of carbon monoxide in the atmosphere was selected because:

It is the best combination of sensitivity, portability and time economy. It will give a distinctly positive test with concentrations as low as 1 part in 10,000; a brief case will hold the apparatus for taking twelve samples; and the analysis of the twelve samples can be completed in the laboratory with the help of an equilibrator in three or four hours.

The average of all carbon monoxide tests was 0.9 parts per 10,000, i.e., less than 1 part per 10,000. The average for repair shops was 1.1 parts per 10,000; for rooms in which small repairs were made incidental to the storage of automobiles, the average was 0.6 parts per 10,000; and in commercial garages storing 5 or more cars the average was 0.9 parts per 10,000.

It is clear that the average condition is not deplorable, although 1 part per 10,000 is just about the maximum that should be tolerated in a room where there is an eight-hour exposure to the gas.

Many of the garage proprietors reported that employes complained of headaches which they believed were caused by the gas; but there were only a few places where the condition became so pronounced that employes had to leave their work.

In almost every case where an excessive amount of carbon monoxide was found, there

was also a distinctly visible smoke cloud and also a strong odor noticeable upon first entering the room.

Mechanical ventilation was almost unknown in the shops covered—only one exhaust system in all of the 71 shops. Five had small propeller fans installed in windows. A few of the shops were equipped with flexible pipes which were slipped over the end of the exhaust pipe to conduct the noxious gases outside the building. This system gave good results when used but, of course, is not effective in large commercial garages where machines are in motion. Two illustrations and three tables accompany the article. —Carroll M. Salls, *Indust. Hyg. Bull.*, N. Y. State Dept. of Labor, 4, 5:17–20 (Nov.), 1927.

Tuberculosis in Relation to Housing and Industrial Conditions—Whether tuberculosis in the adult represents the awakening of an infection acquired during, but latent since, childhood, or a new infection, is under dispute. Sure and certain knowledge concerning tuberculosis is not extensive. It may be summed up in two statements:

1. Tuberculosis is an infection.
2. This infection is acquired during life.

In this country, during the war period, the rise in tuberculosis mortality was confined to the ages 15 to 30 years, was particularly investigated for women, and shown to be in direct proportion to the extent they were called upon to perform munition work. The evidence is conclusive that nutrition, or rather malnutrition, is a factor ruling mortality from the disease in early adult life. In spite of the fact that following the war inadequate housing was at its height, a decided fall in the mortality has occurred and the trend of the pre-war fall has been resumed. The fall, just as occurred in the 50 years or so previous to the war, was coincident with a rise in the value of real wages. Apparently unhygienic environment is of far less importance than mal-

nutrition, so far as tuberculosis is concerned.

Heavy work on entering industry and low pay, which represents an inadequate dietary, predispose to the disease in early adult life. Industrial life for most females terminates with marriage, but for males it continues throughout life. Any difference, then, which exists between the mortality from tuberculosis of males in middle life and that of females, may reasonably be ascribed to industrial conditions. The difference is well known to be pronounced and to be far more pronounced in industrial districts than in rural areas. Today the stronghold of tuberculosis, when estimated by the mortality from phthisis at age periods per 1,000 living, is found among males of middle age in industrial districts; but mortality at this period of life may reasonably be held to represent the cumulative effect of industrial life as lived during the last 30 years. The effect of shorter hours of work, customary today, will only become manifest as years pass.

The factor of infection is found dominating the predisposing factors of malnutrition and wear-and-tear, which can only act by modifying the power of resistance to infection. The wear-and-tear factor—silicotic fibrosis—in the Rand Gold Mines is so specific and intense, that it might sociologically have been expected to dominate the infection factor; but it has been found absolutely necessary, in order to bring the occupational risk under control, to minimize and, if possible, eliminate tuberculosis infection from the industry. Through periodical reëxamination every 6 months of all European labor, excellent results are being obtained, and, when native labor is as strictly supervised as European, the industry will be freed from its scourge. *Control of an infectious disease can only be acquired by controlling exposure to infection.*

The conclusion presented is that *the amount of tuberculosis infection has*

been diminishing; it may still be ubiquitous, but it is less intensive. We must recognize the tubercle carrier, just as we do the typhoid carrier, and, although we adopt every means to maintain a stronger resistance, we must eliminate the infected from our factory industries and place them in industrial colonies.—Edgar L. Collis, *Med. Off.*, Aug. 6, 1927, pp. 59–61.

The Trend of Occupational Mortality in the United States—The compilation of mortality rates by industry is a difficult if not an impossible task, so far as American vital statistics are concerned. Dr. Pedley in this paper presents a consideration of the statistics of the City of New York for the year 1924 of the Metropolitan Life Insurance Company and of the United States Census Bureau, classified not according to occupation, but for occupied persons by various causes of death. Instead of attempting to arrive at mortality rates Dr. Pedley uses the proportionate mortality method for estimating the severity of the various diseases. That proportionate mortality data is open to certain criticisms and possesses certain fallacies is well known to statisticians, and Dr. Pedley is fully cognizant of the limitations of his data in this respect.

From this data it is obvious that tuberculosis is still excessive in industry as contrasted with the country as a whole, but cardiac diseases have deposed tuberculosis from its position of first prominence.

Dr. Pedley further points out the very interesting fact that the relative proportion of cancer among occupied persons is actually less than among unoccupied persons. It is true that this may in some measure be brought about by the listing on the death certificates. The increase in proportionate mortality from cancer among occupied persons from the year 1909 to 1923 is no greater than that

among the general population.—Frank G. Pedley, *J. Indust. Hyg.*, 9, 11:475. (Nov.), 1927. L. G.

Report of a Case of Injury to the Skin and Eyes by Liquid Sulphur Dioxide—This brief paper presents the review of a case of a workman who, while attempting to open a valve on a tank containing sulphur dioxide broke the pipe leading to the tank, thereby permitting this substance to cover certain parts of his head and body. Very little injury was inflicted upon the parts of his body which were covered by clothing, but his eyes and face were rather severely injured. Considerable edema of the eyelids with blistering of the skin was present over most of the face. The cornea of the right eye was almost completely denuded of epithelium and there was marked conjunctival injection and chemosis present. Treatment consisted of boric acid wash, atropine and oil installations. After 5 weeks, vision in each

eye was $\frac{20}{100}$ and after 4 months, the vision was $\frac{20}{20}$.

The author's observations

in this case lead him to believe that the ill effects of exposure to liquid sulphur dioxide are due to a rapid freezing of the tissues and not to any escharotic action.—B. R. Kennon, *J. Inst. Hyg.*, 9, 11: 486. (Nov.), 1927. L. G.

Pulmonary Asbestosis in its Clinical Aspects—Sir Thomas Oliver points out that with two exceptions, so far as he is aware, there has not been anything written on the subject of pulmonary asbestosis in Great Britain. He therefore takes this opportunity to present the histories of two females whom he examined and found to be suffering from this disease. The first patient, age 48, was forced to give up work on account of increased physical debility and shortness of breath. Her lungs showed ab-

normal breathing sounds and the presence of moist, tinkling sounds suggestive of cavitation. The respiratory capacity was found to be 1 inch. The apex beat was felt external to the nipple, which finding, considered along with the marked accentuation of the second sound of the heart over the pulmonary artery suggests to Dr. Oliver that fibrotic changes have already taken place in the lung.

The second patient, age 39, an asbestos worker for 18 years, developed a cough and bronchial asthma, and finally stopped work because of the loss of considerable weight in the early months of a pregnancy. The cough persisted throughout this time, but the infant daughter who is now 14 months old was found to be healthy and well developed. There is a noticeable shortness of breath on slight exertion and the presence of morning cough with expectoration. The heart is normal, but the second sound over the pulmonary artery is distinctly accentuated and moist rales were found at the base of the lungs.

In both cases the sputum was found to be negative for tubercle bacillus. The disease resembles silicosis in pronounced shortness of breath on slight exertion and deficient respiratory capacity.—Sir Thomas Oliver. *J. Indust. Hyg.*, 9, 11: 483. (Nov.), 1927. L. G.

Mental Hygiene in Business—We all promptly recognize the following types of children: the bashful, recluse, sensitive little fellow; the boastful, bullying sort who makes life miserable for his playmates; the deceitful boy; the boy with the uncontrolled temper; the youngster who pulls the cat's tail when no one is looking; the misfit who seems to have the faculty of always doing the wrong thing and being more or less constantly in difficulties; and so we might continue with a great number of well recognized types of personalities. Too well we know these same children in later life.

These are problems in human behavior; they are personality problems; they are problems in the adaptation of the individual to his everyday environment; they are problems for mental hygiene.

We have no argument with the principles of physical hygiene which have contributed so much to the well-being and longevity of our generation; education, moderation, cleanliness, regularity are the cornerstones. The development of mental hygiene has proceeded quietly, logically and effectively until it has become an integral part of the fabric of our everyday educational, social, political and business life.

Is it not incumbent on the leaders of industry to acquaint themselves with and make use of the principles and practices of mental hygiene?—Abstract of remarks by Dr. Quinby before the Executive Committee of the Associated Industries of Massachusetts. *Industry*, XIX, 10 (May 7), 1927: (Quoted from *The Human Factor*, 3:11 (July-Oct.), 1927.

The Medical Inspection of Factories—Commenting upon the condensed report of the conference held at Düsseldorf in 1926, published by the International Labour Office, the *Medical Officer* says:

Sir Thomas Legge, who represented Great Britain, gave an excellent report of the state of medical inspection of factories in Britain, which has the oldest scheme in existence and which has not been altered materially since 1844. Sir Thomas sees the necessity for a revision, and briefly indicated along what lines he considers such reconstruction should proceed. We have elsewhere shown dissent from many of Sir Thomas's ideals, but here we are concerned not with details, but with the broad basis of factory medical inspection, about which there is no difference of opinion amongst experts, as is shown by the resolutions of the conference being carried unanimously.

These resolutions are as follows:

Principles which should govern the organization of medical factory inspection in all countries:

1. The broadest freedom of access to all

places where work is done. Freedom of investigation of all kinds: questioning, examination of the personnel, taking of samples, etc.

2. The privilege of free expression of opinion to responsible authorities without submission to the censorship of non-medical intermediary authorities.

3. Compulsory consultation of medical inspectors by all constituted authorities on all questions concerning the health of the worker as such.

ADMINISTRATIVE POSITION

1. It is desirable that medical inspectors form an organization independent of other similar administrative organizations.

2. Medical inspectors should exercise sufficient authority to ensure compliance with regulations affecting the health of the worker as such.

3. It is the duty of the medical inspector to make proposals for regulations specially connected with the personal hygiene of the worker as such directly, and not through any other official.

4. Rules should be drawn up for the coöperation of medical inspectors with other officials appointed to supervise industrial establishments of any kind.

5. This coöperation should be based on the fundamental principles of administrative equality of the different organizations taking part in factory inspection.

We draw attention to Nos. 1 and 3 of the administrative position. To make No. 3 effective, coöperation with general public health administration is essential, and this could not be done without some modification of No. 1. The main idea before the conference was to divorce medical from other inspectorial duties. Nothing, in our opinion, would render this more feasible and acceptable than transference of the medical inspectorate of factories from the Home Office to the Ministry of Health in this country and

its inclusion in the general organization of the nation. Sir Thomas Legge suggests certain objections to this, but we submit that his objections result from a misconception, and that if ever we get down to consider the matter as a practical proposition, he will see his way to withdraw any opposition he may put forward.

The medical inspection of labour seems to us to resolve itself into three distinct but closely connected factors: that of the factory itself; that of the personal environment of the workers in the factory, and that of the outside environment and private hygiene of the worker. In the last category, it might be stated, as an example, that though bad housing conditions are always detrimental they cause far less serious trouble to agricultural labourers than they do to mill operatives. In fact, the inspection of factories and of factory workers as factories workers cannot well be separated from the general medical supervision of the workers as citizens, though it is undoubtedly a special department, requiring of its practitioners specialized training and experience.

The last passage of the report of Professor Holtzmann of Baden is noteworthy:

"Emphasis is to be laid on the importance of the medical inspector's duties as an instructor in the Technical High School. Young engineers, engaged in acquiring practical experience, are enabled in this way to obtain a knowledge of industrial hygiene necessary for their duties.

"The little brochure is replete with interesting observations and the whole forms a very good epitome of modern factory practice."—*Med. Off.*, Oct. 22, 1927, pp. 183–184.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Nutritive Properties of the Mung Bean—The mung bean, grown throughout southern Asia as well as other tropical countries, is the principal constituent, either dried or germinated, of chop suey, and preliminary experiments indicate that it can be grown in certain semi-arid sections of the United States. The beans used in experimental feeding were the solid green seed which contained 23.31 per cent protein and 9.31 per cent moisture. The protein content was further studied showing the amino acids and their distribution.

On a ration containing 60 per cent of the bean, representing approximately 14 per cent protein supplemented by sodium chloride and calcium carbonate made up with dextrin to 100 parts, rats were enabled to grow to maturity and to reproduce young, many of which were weaned. The growth, however, is somewhat below normal and reproduction limited.

A second set of experiments was conducted using the optimum protein level to investigate the vitamin content of the seeds, and a third experiment was carried out to determine whether there was a deficiency other than that of sodium, calcium and chlorine. Vitamin A was found to be present in amounts necessary for normal growth, indicating the superiority of this bean in that respect to most seeds. Vitamin B is present in sufficient amounts when the bean composes 60 per cent of the ration. It was found that the addition of sodium, calcium and chlorine completed the mineral requirements. To determine the effect of cooking, beans were autoclaved at 15 pounds pressure for 1, 2 and 3 hours, then dried and fed, vitamin A being added in all cases. Heating for 1 hour indicated a

slight improvement, but the seeds heated for 3 hours were decreased in nutritive value of the protein. It is concluded that the mung is a superior type of bean nutritively but not adequate as a sole source of protein.—V. G. Heller, *J. Biol. Chem.* 75:435 (Nov.), 1927.

Zinc and Normal Nutrition—Various plant and animal substances were examined to determine the zinc content corroborating the previously reported widespread presence of zinc. Feeding experiments were conducted on white mice, applying a standard basal diet for control. This basal diet was varied to exclude so far as possible zinc, and was later supplemented by known amounts of zinc, 0.02 mg. per mouse per day in one group, and 0.04 mg. per mouse per day in the second. In each case the zinc was added as a solution of the sulfate. Laboratory-bred mice, uniform in weight, were used for experiments and so far as possible comparison made within litters. Tables are given showing the rate of growth of the various groups over 20, 45- and 70-day periods after the mice had reached 10 gm. of body weight. It was found that there was a retardation of growth when the animals were fed on the zinc-low diet. The addition of 0.02 mg. zinc per mouse per day resulted in a stimulation in growth as compared with the zinc-low diet. With the larger amount, 0.04 mg. per mouse per day, the same stimulation and growth was not found, and there was more irregularity than in other groups. Comparing the zinc diet with the control diet, it was found that while there was some stimulation, it would not alone restore the food mixture to the level of the control.

In addition to the growth experiments, an examination was made of the zinc content of animals at various ages on the stock diet and of animals at the age of 70 days after reaching 10 gm. body weight, in the experimental diets. The analysis indicated that the animals on the zinc-low diet had a distinctly lower zinc content than those on the control diet. Animals fed 0.02 mg. per mouse per day showed a zinc content somewhat above the animals on the zinc-low diet. With the feeding of the larger amount of zinc, the amount retained was increased for the males, but not for the females. In both the zinc fed groups, the zinc content was comparable to that of the control and those on the stock diet. There is apparently no storage of zinc to any extent in the growing animals. It is concluded that while the addition of a small amount of zinc may cause a slight stimulation in growth, the addition of zinc alone to a food mixture low in the metal is not sufficient to equalize this diet to standard, probably due to the fact that the value of the zinc cannot be ascribed to the metal itself but that it is associated in function with other metals present in small amounts.—Rebecca B. Hubbell and Lafayette B. Mendel, *J. Biol. Chem.* 75:567 (Nov.), 1927.

Feeding Experiments With Plants at Different Stages of Development
—III. Synthesis of Vitamin in Plants—In this continuation of the study previously noted (E. S. R. 53:766), ungerminated, germinated, and green corn were compared as to content of vitamin A by using an equal number of seeds instead of equal weights of the three materials. One group of five rats whose weight had become stationary on a diet deficient in vitamin A was given 6 seeds of ungerminated corn per rat per day in addition to the basal diet, another group of five received the equivalent of 6 seeds of germinated corn, and a third group the green seedlings. Within 81 days all

of the rats in the first two groups had contracted xerophthalmia and eight had died, while all of the rats in the third group were in excellent condition and were gaining in weight. This is thought to indicate a synthesis of vitamin A during the development of the green color.—M. Karshan, F. Krasnow, and B. Harrow, *Soc. Exper. Biol. & Med. Proc.* 24: 765, 1927. Abstract, *Exper. Sta. Rec.*, 57:789, (Dec.), 1927.

Food Poisoning—The Malcolm Morris Memorial Lecture was delivered by Dr. W. G. Savage who discussed the subject of food poisoning. The simplest type is that caused by the consumption of a definitely poisoned plant or animal such as, for example, mushrooms, or apples sprayed with arsenicals. In 1922, 200 people were poisoned by apples which had been cooked for hours in a zinc container. Another instance of poisoning was caused by the contamination of sage used for stuffing, with belladonna leaves. These outbreaks, however, represent a very small proportion of all poisoning, most of which is caused by bacteria. Dr. Savage pointed out that ptomaine poisoning is a misnomer. While chemists have been able to extract toxic ptomaines from decomposed material which caused violent symptoms when injected into animals, no poisoning of this type is traced to food which is not decomposed and at least three-fourths of the outbreaks in England are due to bacilli of the *Salmonella* group. This group multiplies rapidly in warm weather and does not as a rule cause visible changes in the food but produces very irritant toxins. A study has been made of 200 outbreaks to determine the varieties of food responsible for the ingestion of the *Salmonella* bacteria. It was found that 30 per cent were due to canned foods, 7 per cent to milk, 8 per cent to milk products (mostly ice cream and cheese), 27 per cent to made-up meats, 4 per cent to manipulated foods

like stuffed meat, 16 per cent to fresh meat, 4 per cent to fruit or vegetables, 3 per cent unclassified. Seventy-two per cent were traced to foods which had been handled in some way by man.

One outbreak in 1923, in which hundreds of people were sick and one died, was traced to ice cream having been cooled in a filthy place and sold through the streets in hand barrows. Some *Salmonella bacilli* were isolated from this ice cream. It was found the *Salmonella* toxin could be boiled for an hour or longer without destroying its toxicity. Botulism is somewhat infrequent in England. An outbreak occurred in 1922 caused by eating sandwiches containing wild duck paste. *Salmonella bacilli* are not normal to the human intestine but are found in diseased animals; it has been shown that botulism can arise from drinking the milk of diseased cows. Dr. Savage believes that the legislature has not provided for sufficient control over preparation and manufacture of made-up foods and believes there is urgent need for registration and licensing of premises where such processes are carried out, with periodic inspection and the power to close if necessary.—*Lancet*, 2:900 (Oct. 22), 1927.

Studies on the Effect of Abundant Cereal Intake—Feeding experiments on young albino rats have shown that when suitable supplementary foods are employed, whole grain cereals and at least one milled wheat breakfast food product when supplying as much as 84 per cent of the calories of the diet result in excellent growth, reproduction, lactation and general satisfactory physiological condition. Diets containing as much as 93 per cent whole grain calories approximate those of current normal standards, indicating that the limits of whole grain cereals in the diet are extremely liberal provided the diet is otherwise properly balanced. While the application of the results in rat feeding experiments to

human nutrition should be made with reservation, the science of nutrition would not warrant the conclusion that the results as reported in this paper do not have a practical bearing on nutrition in man. It is the conclusion that this work demonstrates the feasibility of the inclusion of cereal in the dietary in much greater amounts than is now common in this part of the world.—George R. Cowgill, Margaret H. Jones, Robert A. Frisch and G. P. Jackson, *J. A. M. A.*, 89:1770 (Nov. 19), 1927.

Relative Nutritional Value of White and Brown Breads—Professor Friedberger of Berlin carried out experiments to determine the nutritive value of various kinds of bread, particularly white bread, compared with *schwarzbrot* (brown bread, rye bread). "*Klopfcrbrot*" (boxer bread) produced the greatest increase in weight of rats of the same weight and the same litter, and white bread the smallest increase. Comparing the inside of the loaf and the crust it was found that white bread crust caused loss in weight. It was found that *zwieback* was responsible for a constant loss in weight up to their relatively early death which was ascribed to the great heating and double baking. When the animals were fed *einback*, which is the loaf before subjecting to the second baking, slight increases in weight were found, confirming former experiments indicating the change in weight producing value of food due to heating and showing the great variation in the weight producing value of bread in common use. While, on the basis of analysis of the food stuffs, it would follow that white bread is the best utilized in human economy, there is some doubt as to whether this should be the criterion in judging quality in an article of diet, believing to the contrary that, from the standpoint of weight gains at least, bread from the whole grains are to be favored.—*J. A. M. A.* 89:1798 (Nov. 19), 1927.

Digestibility of Potatoes as Influenced by Methods of Preparation—

A study was undertaken in order to determine whether or not fried foods are more indigestible than foods prepared in other ways in view of the universal application of frying in the preparation of food. Potatoes of the Early Ohio variety were used and kettle-rendered pure lard employed for frying. The potatoes were cut in uniform pieces and cooked by three methods—French fried, pan fried and boiled. The digestibility of these potatoes by different methods was determined in vitro, and studies were also made in the case of 2 dogs, 4 men and 1 woman of the time required for the emptying of the stomach of potatoes prepared by these methods. It was found that the starch of the potatoes fried in cold fat is more easily digested by pancreatic juice than boiled potatoes or hot fried potatoes. In the case of the dogs, boiled potatoes were emptied from the stomach more rapidly than fried potatoes, there being no appreciable difference in this case between French fried and pan fried. In 4 of 5 human subjects, potatoes were emptied from the stomach at the same rate whether boiled or fried. A delay in emptying was found, however, if the potatoes, after cooking take up excess fat or fat is added as gravy or butter. It was also found that the gastric motility is more susceptible to

the inhibitory action of fats in some individuals than in others. The conclusion is reached that in an average normal individual, fried potatoes, unless steeped in fat, are no more likely to cause digestive disturbances than boiled potatoes.—Bessie Boggess and A. C. Ivy, *J. Home Econ.*, 19:496 (Sept.), 1927.

Serum Against Mushroom Poisoning—Fatal mushroom poisonings are due to the alkaloid phalline, muscarine being much less dangerous owing to its emetic action. Symptoms of phalline appear about 10 hours after ingestion of the poison when it attacks the blood and produces hemolysis. M. Dujarric de la Riviere, professor at the Pasteur Institute, has prepared a serum from the horse for treatment of mushroom poisoning. Hypodermic injections of this serum are highly prophylactic and of therapeutic value when applied to laboratory animals.

In one case of a family in which three had been poisoned simultaneously, the physician was able to secure but two ampules of the serum and administered these to the most seriously affected, while the third, who had not received the injection, died. The Congress of Hygiene passed a resolution recommending supplies of this serum be kept in hospitals and for the accommodation of physicians.—*J. A. M. A.* 89:1529 (Oct. 29), 1927.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

Etiology of Respiratory Disease in the City and Country Schools of New York—Dr. Lincoln presents a study of school absences from respiratory infections. One hundred and thirty-two children, aged 3 to 12 years were studied. Stool examination, urinalysis and physical examination by the physician were made in each case. Chest roentgenograms were made in many instances.

Preventive measures were taken during the school years 1921 to 1924 inclusive and were very detailed. In spite of these measures the rate of absence due to respiratory diseases, colds, tonsillitis, grippe, influenza, etc., was not greatly reduced. This compares with the experience of other physicians. Age and season, as seen by the reports, were determining factors to some extent.

Following the apparent failure of this program an intensive study was made of the 1923-1924 period. One striking point came up: The children in two school-rooms that were constantly reported to the physician's office as "too cold," showed a marked decrease in the rate of morbidity from colds. There was no correlation between the state of nutrition and the amount of respiratory disease. Conclusions are quoted in full:

1. A statistical study of absence from school due to respiratory diseases is presented.

2. Environmental factors in the classroom and home of each child, were studied, as well as the results of the physical examinations and a careful survey of his diet.

3. The only direct correlations obtained were between absences due to respiratory disease and the presence of abnormal conditions in the upper respiratory tract and between absences due to respiratory disease and the amount of carbohydrate in the daily diet of the child.—Edith M. Lincoln, M.D., *Am. J. Dis. Child.*, Sept., 1927.

Amalgamation of Child Welfare and School Medical Work—Amalgamation of school and preschool service has advantages and disadvantages. Dr. Clark discusses both but presents the desirability of such coöperation as practically inevitable in view of future development along lines of unification of public medical work in local affairs.

To his way of thinking "The completion of the supervision of child life in public medicine is the most pressing demand of our time"—the preschool age being "a vital one in preventive medicine."

He feels that school medical service should be transferred to the public health committees. It would then be looked upon "as a primary health service and would in no sense be in danger of relegation to a place of secondary importance."

Dr. Cassie deals wholly with "points of immediate practical importance," and feels that amalgamation is not desirable from the administrative side as it would constantly interrupt instruction of mothers in child care. This work is done by "infant visitors" who are "specialists among nurses" and if their work were to be combined with school nursing interruptions caused by "epidemics of infectious diseases, periodic school examinations, etc.," would be frequent. (This argument, by the way, is certainly well illustrated in much of our local nursing work in our own states. Also, the nurse's preference would, very humanly influence her work.)

Points in favor on the clinical side are summarized as follows:

1. A greater variety of work.
2. School work can be done in the morning when child welfare clinics are not so well attended.

3. In county areas a saving of time and travelling expenses can be obtained by careful organization.

4. Continuity of records.

R. Veitch Clark and Ethel Cassie, D., *Pub. Health*—Sept., 1927.

Five-Year Infant Mortality Study
Buffalo, N. Y.—Dr. Hollingshead's report of the infant mortality in Buffalo covers the period 1922–1926.

In the preceding years, 1910 to 1921, the number of infant deaths under 1 year dropped from 165 to 94 per 1,000 live births, but in 1922 the rate went up again to 102 and this stimulated the interest of the city department of health which asked the Buffalo Foundation to make this study.

The data on birth and infant death records for the city for the 5 years have been studied by wards and special districts, by nationality of parents, by cause of death and age at death, by hospitals at which the births occurred, and by physicians in attendance.

The study by wards is a valuable method as by such means the city sections most needing attention are given more attention. In the eight wards the infant mortality rate ranged from 125 per 1,000 live births to 62. Resident and non-resident mothers were separately grouped—also mothers born in Italy, in Poland, in Buffalo, and in the United States outside of Buffalo.

With the Polish-born mothers the infant mortality was 122 per 1,000 live births. With the Italian-born mothers, it was 87, and with the American-born mothers 85.

An interesting point was the fact that 6 per cent of the deaths of babies of Buffalo-born mothers occurred under 2 months, while only 37 per cent of the babies of Polish-born mothers and only 1 per cent of the babies of Italian-born mothers occurred at this early age. The question arises how much of this might be due to lack of breast feeding on the part of the American-born mothers. The causes given were premature birth, in-

juries at birth, and "other conditions of very early infancy."

More babies died of respiratory diseases in the group of mothers born in Italy, while digestive diseases caused a higher proportion in the group of mothers born in Poland. Twelve per cent of deaths of infants of Buffalo-born mothers were reported caused by malformations as against 6 per cent among infants of the Polish-born mothers and 5 per cent among those of mothers born in Italy.

The negro mothers' babies showed an infant mortality of 120 per 1,000 live births.

Midwives attended 16 per cent of all births and lost 2 babies under 2 weeks of age for each 100 babies attended.

Thirty-three per cent of the babies were hospital born. Infant mortality rates in hospitals varied from 10.9 to 1.3. In all strictly maternity hospitals the infant mortality rates averaged below 4.5 per 100 deliveries.

Two groups of physicians were studied. The first group of 20 had an average infant mortality of 4.6 per 100 live births. The highest mortality was 8.6 babies under 2 weeks of age in each 100 births attended. The lowest figure was 1.5 per 100 live births. These physicians average 700 births each for the 5-year period.

The second group of 33 physicians had an average rate of 4.3 per 100 deliveries. This group averaged 290 births each for the 5-year period.—*Pub. Health Rep.*, Nov. 25, 1927.

The Toothbrush in Preventive and Curative Dentistry—One of the greatest achievements in the scope of preventive and curative dentistry—and the one most often neglected by the general practitioner—is the toothbrush.

Tooth brushing is an important factor in treatment, because it is the treatment that patients receive most frequently, approximately twice a day, while they visit the dentist once or twice a week

during active treatment and only once every month, two months, or sometimes six months to a year during passive treatment. It is of importance not only as a curative agent in removing disease but as a therapeutic agent in preventing disease.

Tooth brushing is necessary not only to cleanse the teeth, which I believe was formerly the primary function of the toothbrush, but also to stimulate the gum tissue and consequently the blood supply to the gingiva, the alveolar bone, the pericementum or peridental membrane and the tooth itself through the connection of the apical blood vessels with those of the gingival mucosa, the bone and the pericementum.

Quite often with proper brushing we see the tooth take on a luster. This is due to the removal of the mucous deposits, and mainly to the stimulation of the blood supply to that tooth indirectly. If the diet were such that the teeth and the peridental tissue received the proper stimulation during mastication, causing the blood vessels to be compressed and dilated, this method of tooth brushing would not be necessary. Just as the muscles in our bodies aid the circulation of the blood by their contraction and relaxation—the contraction compressing the vessels driving the blood out into the veins and the relaxation allowing new blood to flow in—so do we, with the toothbrush, produce a like condition.

We know how good we feel after a work-out at the gymnasium, though this would not be necessary if we led the ac-

tive lives of our ancestors. The gingival tissues of our ancestors did not need stimulation because it was produced by the diet, and since it is absent in our present mode of living, we must produce it artificially. The method has rightly been termed "physical culture for the gums."—Samuel Miller, D. D. S., *Dental Digest*, Dec., 1927.

COMMENT

With the increasing stress that is being laid upon tooth brushing as a means of keeping the gum tissue normal as well as a good health habit and an added factor in preventing tooth decay, school nurses, dental hygienists and other health workers might well improve on their present methods of teaching children to brush their teeth.

The old way of giving toothbrush drills with throat sticks, pencils or fingers on the outside of the face may be effective as a form of military drill but it has very little connection with what the child actually does when brushing his teeth at home. Learning to brush the teeth properly is a serious thing, especially at the age of 6 or 7. A few minutes of personal instruction with each child or to a group of three or four in a place properly equipped with a mirror, running water and a good tooth brush, followed by periodic inspection, with proper rewards to help this brushing to become a habit will accomplish more in a few minutes than toothbrush drills from kindergarten to high school.—Eleanor B. Gallinger, D.H.

PUBLIC HEALTH NURSING

MIRIAM AMES, R.N.

Canadian Red Cross Outpost—rural hospitals are no longer an experiment in Canada. A thrilling glimpse is given us by S. Leslie Bell, R.N., of the kind of experiences met with by the public health nurses who have elected to do pioneer trail-blazing in the sections of the provinces remote from cities.

The establishment of Outpost Hospitals is part of the constructive work undertaken in the peace-time program of the Red Cross. There are three types:

1. The center of field nursing. The nurse works in the homes and schools of the district, but no provision is made for inpatients.
2. The rural Outposts with accommodation for one- or two-bed patients, but with field nursing as the chief work of the nurse.
3. The Outpost in a village or small town which functions as a small hospital.

A request for the establishment of an Outpost Hospital comes from a community where medical, nursing and hospital facilities are lacking. The need of the community is determined first by means of a thorough survey to ascertain present conditions and to determine what might be expected in the future. The community is asked to furnish the building and as much of the equipment as it can. Other agencies occasionally assist in meeting some of the expense, and the Provincial Division assumes a share of financial responsibility for an initial period, which differs according to the need of a particular locality. After the initial period, the service is continued but under a different plan. The Red Cross continues to operate, but the community guarantees to refund a percentage of the operating deficit. The community undertakes ultimate maintenance of the Outpost service as soon as it is able. No Red Cross Outpost or rural hospital is oper-

ated in any district unless an active branch of the Red Cross exists, or is established, to coöperate with the Divisional Office in operating the Outpost.

During the 7 years of Outpost activity, 32,219 patients have received treatment at or through these Red Cross Outposts.

The governments of the provinces in which Outposts are established recognize them as hospitals according to law, and the ordinary per diem allowance for patients is made. Thirty-nine Red Cross Outpost Hospitals are already operating throughout Canada, and there are requests for many others which could be established to advantage, provided the expense for establishment and upkeep could be met.

When the patient cannot go to the Outpost, the nurse goes to the patient. Where the physician is too far away to be available, the judgment of the nurse is called upon to an extraordinary extent. Last year, 3,088 patients received over 30,000 days of attention of the Red Cross nurses. Seven hundred and forty-three babies were born, most of whose mothers would have gone unattended. Both preventive and curative work are done.

The contribution which Canada is making to the cause of public health is far-reaching; not only has it benefited the Canadians, but other Red Cross societies have recognized the value of this plan and are establishing similar services.

NOTE: The plan for the establishment of rural hospitals by the Commonwealth Fund in the United States is comparable—the nuclei of our future public health nursing centers in rural communities—S. Leslie Bell, R.N. *Am J Nursing*, Nov., 1927

Learning By Suffering—A large medical school has decided that the theoretical study of diets and of diseases is

not enough. Just because a meal contains the proper number of calories, properly distributed among the dietary essentials, does not mean that such a meal will be palatable to the patient. Therefore, after the student plans the meals which he considers necessary, the dietician selects one "usually the most unpalatable and poorly balanced." The prospective physician then has to weigh out the food and eat the meal.—*Learning by Suffering*, Editorial, *J. A. M. A.*, Oct. 29, 1927.

First Periodic Health Examination—The City Club gave over four days of the week of November 14 to the work, and in that time examined 57 women. Of that number 56 had made the preliminary applications, sent in the required specimens for routine laboratory tests, and otherwise complied with the requirements. The 57th applicant made the journey from another state for the express purpose of having the examination. More than 50 women were turned away because the time allotted did not permit more examinations to be made.

It should be said in passing that one of the reasons that the carefully planned schedule worked so well was that not one of the women who had applied broke her appointment or was late. Truly a record of feminine achievement!

The examinations were conducted by young physicians under the direction of Dr. Roger I. Lee. A thorough physical examination was made, and for those who specified a preference a woman physician was assigned. Two volunteer nurses prepared patients, weighed, measured, took histories, and were ready for any additional service. Members of the committee, Dr. Mary R. Lakeman, Dr. Marion Coon and Dr. Susan Coffin, kept regular hours at the club each day, and were the connecting link between doctors and patients. One feature particularly appreciated by the doctors was that the telephone switchboard arranged a special

service by which they were constantly in touch with their own offices.

Four rooms and two bathrooms on one floor in the club house at 5 Walnut Street were assigned to the work. A special table was provided in one of the bathrooms for gynecological examinations.

The results proved conclusively that the health examination was worth while. Proper health habits such as well balanced diets and sufficient rest were all that were needed in most cases to assure good health. However, in 3 cases serious conditions previously unknown and demanding immediate attention were discovered.

Dr. Lee plans to send a follow-up letter to every woman who was examined, explaining her condition and making his recommendations. It is hoped that Health Week will presently become a fixed period on the yearly calendar.

An account of the First Periodic Health Examination is given by Elizabeth Ellam, Publicity Director of the Women's City Club of Boston. This new activity sets an example that might well be followed by women's organizations with lasting benefit to themselves and their communities.

Advance in Flood Area—The old saying "no loss without some small gain" can be well applied to the Mississippi flood district. The gains as far as public health is concerned are indeed many. The prompt action of the Red Cross at the time of the flood, cooperating with national, state and local health agencies, demonstrated to hundreds of thousands the value of preventive medicine. Instead of disease following in the wake of the flood, the health conditions are better than they have been for years.

While the results of this unplanned, unexpected demonstration are still fresh in the mind, permanent health units are being formed by the U. S. Public Health Service and the Rockefeller Foundation, in cooperation with the state departments of health. To insure competent personnel for these health units, the

Rockefeller Foundation has opened a training center in Indianola, Miss. By September 5, 12 physicians, 10 nurses, and 19 sanitary officers had completed their training. On that date, there were still in training 11 physicians, 13 nurses, and 18 sanitary officers. Also applications for this course had been made by 5 physicians, 11 nurses and 1 sanitary officer.—Public Health Advanced Twelve Years in Flood Area, by William DeKleine, M.D. *Red Cross Courier*, Nov. 1, 1927.

Studies Children's Food Habits—

Eating at the family table at too early an age, overweight during infancy, eating insufficient food, staying up too late at night and idiosyncrasies about eating were among the causes of malnutrition revealed by a study of 30 children reported by Dr. Louis W. Sauer in the *Journal of the American Medical Association*.

Bringing a child's weight up to normal results almost without exception in improvement in chronic ailments, Dr. Sauer said.

Good results in the treatment depend on removal of the underlying cause, cooperation on the part of the patient and the family, eating sufficient food of the proper kind and establishment of proper rest, exercise and play.—*Hygeia*, Nov., 1927.

When Measles Threatens—A physician is often faced with the need for convalescent serum which he is not able to obtain. Parents are many times unwilling to have their children give blood for others outside the family. In family epidemics, the school child is usually the one who contracts the disease and exposes his smaller brothers and sisters, to whom measles may be fatal. ("More

than 90 per cent of deaths from measles occur under the age of 5 years and 75 per cent under 2 years.")

It has been found in a series of 7 cases that blood taken from a school child sick with measles one or two days after the return to normal temperature and injected into the gluteal muscles of younger children five or six days after exposure resulted in 6 cases of modified measles. In one, measles did not occur.—Modified Measles, The Use of Convalescent Blood From A "Family Donor," by Roy P. Forbes, M.D., and Berryman Green, M. D. *J. A. M. A.*, Nov. 5, 1927.

Change in Personnel, Advisory Committee—At the 56th Annual Meeting of the A. P. H. A. in Cincinnati, October 17-21, the Public Health Nursing Section recommended to the Committee on Administrative Practice that a sub-committee on public health nursing be founded. This sub-committee will confer with the main committee in relation to its studies and findings and render such assistance as is necessary to the Committee on Administrative Practice.

It was voted that the committee to study and report on Advisory Committees for Official Public Health Nursing be continued with a change of personnel to study the urban rather than rural needs. This committee will consist of Clyde C. Slemmons, M.D., Henry F. Vaughan, D.P.H., Francis X. Mahoney, M.D., Mary Gardner, R.N., Cora Templeton, R.N., Amelia Grant, R.N., Mrs. George Hunter, Mrs. C.-E. A. Winslow, Mrs. Frederick S. Roth and James A. Tobey, Dr.P.H.

The section voted to discontinue the Committee on Annual Reports since the subject of Annual Reports is being considered in relation to the entire study of Records.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Health Education in Many Lands—Why do we need health education? What is health education? How is health education being done? Answers to such questions as these, with illuminating examples of the best practice in different countries, are given in the "Health Education Number" of *World's Health* (League of Red Cross Societies, 2, Avenue Velasquez, Paris. 20 cents.). Oct., 1927. There are many illustrations and 2 pages of colored reproductions of European posters on avoidable industrial accidents. We would like to fill this department for several issues with quotations from the contents which include a "Foreword" by Sir George Newman; "Popular Health Education," by Dr. Rene Sand, an interesting review of methods and materials; "How to Awaken a Health Intelligence," by Louis Forest; "Educational Aspects of the Health Demonstration," by J. A. Kingsbury; "Press Publicity," by Dr. Gordon Bates; "Health Education in the Home," by Hester Viney; "A School Health Education Programme," by D. J. Kelley; and book and article reviews. Many health workers will wish to secure copies. Order direct, or send 20 cents to the editor of this department before January 20.

Home-Made Bulletin Board Posters in Racine—Posters better than the average factory bulletin posters are produced as blueprints (11 by 14 inches) by the Racine Board of Health, adopting a suggestion of the Wisconsin Anti-Tuberculosis Association, as "a method of securing small quantities of attractive

posters at low cost." Happily the health officer's wife, Florence Marvyne Bauer, is an artist who works for the department without charge. Says Dr. W. W. Bauer: "These posters are made on tracing paper in India ink. From this tracing we make 100 blueprints and two or three Van Dykes. The blueprints are distributed to 100 of our largest factories where they are placed on shop or employment office bulletin boards. For the Van Dykes we use a standing picture frame with a removable glass back instead of the usual board back, and by setting these in window sills where daylight is transmitted through them we have a most attractive reverse of the blueprint poster. The removable backs of the frames make the subjects easily interchangeable. The State Anti-Tuberculosis Association artist is furnishing us tuberculosis subjects and we are making our own posters on other health topics.

"Another application of this method is the use of Ozalid prints, a comparatively new process which produces a reddish brown positive print direct from the tracing. The Ozalid print is opaque to reflected light but translucent to transmitted light so that it may be used either as a transparency or a bulletin board poster. The cost of these prints exclusive of the drawings is 5 cents each for the 11 by 14 blueprints in quantities of 100. The Ozalid prints are 6 cents each, and the Van Dykes 12 cents. By using the Van Dykes as negatives we can get blue line or positive blueprints, and in this way can secure three varieties of posters and two varieties of transparencies from one original tracing. We are planning to add to our series a number of posters setting

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

orth various health ideas.. By means of this inexpensive process we can have a variety of posters which are strictly our own, much greater than would be possible to health departments with small appropriations where the printing or lithographing process is employed.

"While the supply lasts, we will be glad to send samples upon request to responsible health organizations or workers." (A set of these posters were shown at Cincinnati, October 17-21.)

"He Means Well But . . ."—
 "Some well meant efforts which are bizarre and offend good taste may do harm rather than good. An atrocious poem, song or play, taught to children in behalf of dental health, may not hurt the child, although it represents a poor type of education, but it may disgust the teacher and others. There is also some question in my mind as to whether we are not laying too great stress on speaking campaigns in our efforts at education. Evangelistic methods may have served a good purpose in the past, but the public is getting rather fed up on after-dinner speeches, campaigns and special days."
 —Planning and Organizing a State Dental Program, by W. R. Davis. *Pub. Health*, Lansing, Aug., 1927.

DATES AHEAD

The Annual Motion Picture Conference, January 26-28, New York, N. Y., will include review meetings in projection rooms of film companies. Address: Better Films National Council, 70 Fifth Ave., New York, N. Y.

National Negro Health Week, announced for April 1-8, 1928, is an undertaking which deserves encouragement and help from health agencies. The local committees for Negro Health Week may be very glad to have the benefit of the wider experience of health workers in organizing their campaigns, especially if the helpers stay in the background. Some

state health associations may serve as secretaries of state-wide celebrations. The program as outlined suggests far too many topics, but cooperating health agencies may lead local communities to select certain topics for concentrated effort. Various national agencies offer cooperation which is described in the manual to be issued by the U. S. Public Health Service, Washington, D. C., about the time this notice is published.

International Social Welfare Fortnight, Paris, July 2-13, 1928, offers international gatherings on housing and town planning, child welfare and social welfare, plus the International Exhibition of Housing and Social Progress (June 15-July 15), and the Royal Sanitary Congress and Exhibition (July 10-28), London. There is also the possibility of visiting the great museum on health at Dresden and the one in Munich. The two latter afford many ideas for making exhibits graphic and interesting. Requests for information about any of the above will be forwarded by Committee on Publicity Methods, 130 East 22d St., New York, N. Y.

February—1928

- 5-11. Boy Scout Anniversary Week—
 Address: Boy Scouts of America, 200 Fifth Ave., New York, N. Y.
11. Daniel Boone's Birthday
12. Lincoln's Birthday
 Race Relations Sunday—
 Address: Federal Council of Churches, 105 East 22d St., New York, N. Y.
- 12-18. National Drama Week—
 Address: Drama League of America, 59 East Van Buren St., Chicago, Ill.
14. St. Valentine's Day
17. Founders' Day: National Congress of Parents and Teachers,
 Address: 1201-16th St., N. W., Washington, D. C.

21. 21st Anniversary Celebration: National Child Labor Committee—Address: 215 Fourth Ave., New York, N. Y.
22. George Washington's Birthday. 1927. Twelve health hints, most of them for daily application. Simple, practical, avoiding the suggestions frequently offered which many readers will not accept as being practicable or important.

Nearly all of the above dates offer opportunities for coöperation, congratulation or utilization by health agencies of various types.

The National Academy of Visual Instruction will meet in Boston, Feb. 27-28, 1928. Address: J. V. Ankeney, secretary, State Dept. of Education, Charleston, W. Va.

TIMELY MATERIAL

"Avoid Colds," by W. W. Peter. *Cleanliness Journal*, 45 East 17th Street, New York, N. Y., Oct., 1927. *Free*. "Keep away from walking transmitters who broadcast disease germs."

"Dress According to the Weather." State Dept. of Health, Boston. Press release. Dec. 5, 1927.

"Carbon Monoxide Gas Kills Without Warning," with application to gas ranges and heaters in the home. *The Foreman*, Wausau, Wis. Nov., 1927. *Free*. "You cannot see it! You cannot smell it! You cannot taste it! You cannot feel it!"

Health as described, lauded or defined in ancient and modern literature—in "Health Quotations." *The Campaign*, Iowa Tuberculosis Assn., Frankel Bldg., Des Moines, Ia. June, 1927. 4 cents.

"Guide book for Better Homes Campaigns in Cities and Towns." 10 cents. "Guide book for Better Homes Campaigns in Rural Communities and Small Towns." 5 cents. Better Homes in America, 1653 Pennsylvania Ave., Washington, D. C.

The campaign handbooks mentioned here from time to time contain ideas for alert publicity workers, whether or not they participate in the respective efforts.

"A Daily Dozen." Press release. Oregon State Board of Health. April 19,

TITLES

"It Hurts!" *Hygeia*, Dec., 1927. "The why and wherefore of pain."

"Measles, the Killer." N. M. Bureau of Health.

"A Vanishing Spook—Diphtheria." *Canadian Red Cross Junior*, Toronto, Can. Nov., 1927.

WORDS

Before you again write or speak the word "tubercular" ask for "Tuberculous or Tubercular," a folder by P. P. Jacobs. National Tuberculosis Assn., 370 Seventh Ave., New York, N. Y. *Free*.

TRAINING

Health workers in Iowa and nearby states interested in publicity may wish to attend one of the one- or two-day publicity schools to be conducted at various points in the state by Extension Service, Iowa State College. Address at Ames for details.

SLOGANS

"Cancer, Be Quick"—*Commonhealth*, Boston.

"Time, Tide and Cancer Wait for No Man"—*Commonhealth*, Boston.

POSTERS

A three-section poster bulletin board is offered at \$3.00 by National Safety Council, 108 East Ohio St., Chicago. Space for one 17 by 23 inch, and two 9 by 12 inch posters. Intended primarily for safety and health posters in factories, but may have other uses. Illustrated description *free*.

Subscriptions to *The Poster*, the special authority on the subject, are offered among the prizes announced for a poster contest being conducted by the *North-*

Western Health Journal, St. Paul, organ of the Minnesota Public Health Association. A series of articles on poster-making will appear in the *Journal*, which lists (Nov., 1927) selected sources of information and help—but fails to give prices except in one instance! Anyone wishing copies must write twice.

HOUSE ORGANS

Much health material is distributed through the Red Cross Junior magazines published in many countries. Examples are given in a review of the junior publications in *Our Junior Magazines*, by E. G. Keller. *World's Health*, Paris, June, 1927.

The *Health-O-Gram* is a weekly 1-page mimeographed bulletin started in June by the Newark Department of Health. The items are short paragraphs, some in telegraphic style which makes it easier to be concise. Dr. Craster writes: "It will be issued each week and our circulation is to be built up among local laymen, school teachers and such mediums of publicity as newspapers, magazines, etc. At present, we are only mimeographing 500 each week and have received requests from several citizens and a couple of magazines. The newspapers are quoting it, and I believe it will be used largely in the schools to which we already send daily contagious disease reports, thus eliminating any additional postage for the schools. The heading is a multigraph plate, so the only cost is the paper and a few minutes time each week." Dr. Craster may wish to experiment with colored paper, no two successive issues being alike.

The Listening Post, Penn. Dept. of Health, is now *Pennsylvania's Health*.

Sanidad de Cuba, Department of Health, Cuba, illustrated common fly dangers in its December and February issues.

Cleanliness Journal, Cleanliness Insti-

tute, 45 East 17th St., New York, N. Y. *Free*. "The material may be reprinted, with or without credit."

Dental News, 58 East Washington St., Chicago, Ill. "Official bulletin of the House of Delegates of the American Dental Association."

SCHOOLS AND CHILDREN

A new series of the two-page Health Calendar starts with October, 1927. "Please color me and hang me up where folks can see me." *Free* copy of Wisconsin Anti-Tuberculosis Assn., 558 Jefferson St., Milwaukee, Wis.

The use of a questionnaire among mothers to check the effectiveness of a school safety program is described in "Measuring the Results," by Florence Nelson. *Child Welfare Magazine*, Sept., 1927.

"How the Schools Promote Health"—a nine point summary. *Journal of National Education Assn.*, Washington, D. C. Oct., 1927.

"Questions Prove Inadequacy of Health Instruction," by Laura Cairns. *Nation's Health*, June, 1927. How 46 high schools answered 47 questions, most of which could be given to other groups.

ERRORS AND OMISSIONS

The editor of this department very earnestly solicits corrections of errors of any nature.

Please tell of any omissions of desirable material, or the failure to give sufficient detail in any instance.

Reports of any difficulties in securing copies or in looking up references will be welcome.

Help to make this department both useful and usable, and aid to a better understanding of difficulties in getting all the information and help health workers wish to have.

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR.P.H.

The tumult and shouting begin—With the convening of the Seventieth Congress on December 5, the correlation of federal health activities is once more a national legislative issue. Mr. Parker was planning to reintroduce his bill in the same form in which it was before the last Congress. Submission to the procrastination and devastation of the Director of the Budget will not again be necessary, and further hearings may not be required. It is to be hoped that a favorable report can be secured in the near future from the Committee on Interstate and Foreign Commerce of the House and that the bill can go on the calendar and eventually be passed.

This measure is of importance and interest to sanitarians, but to most members of Congress it is only one of the

nearly 20,000 bills with which they are deluged. A number of national problems of great significance are before this session of Congress and will have to receive prior attention. Thus, flood control, tax reduction, farm relief, and more battleships must be broached, discussed, and fought about, while in the Senate much time will undoubtedly be spent on the question of admitting two of their members-elect, who were a little too lavish in their expenditures in the primaries.

Such progress as there may be on bills of interest to sanitarians will, as usual, be reported in this department. On the first day of the session, more than 5000 bills were introduced. It will be a month before it can be ascertained which of these are concerned with national health.

Scheme No. 12—During the last half century or so, at least eleven proposals of major significance have been advanced for the centralization or coordination of the scattered health activities of our national government. These efforts have been listed by Professor Robert D. Leigh in his admirable book, *Federal Health Administration in the United States*, (page 498), as follows:

1. The Cox plan of 1872 for a bureau of health in the Interior Department.

2. The Bowditch plan of 1875 for a Cabinet department of health.

3. The National Board of Health, 1879–1883.

4. The Committee of One Hundred plan for a Cabinet department, 1906–1912.

5. Representative Mann's plan for a Health bureau in the Department of Commerce and Labor, 1910.

6. The Taft Commission on Economy and Efficiency proposal for an independent health service, 1910–1912.

7. The Smoot bills for a consolidated health unit under an assistant secretary of the treasury, 1912–1915.

8. The Harding-Sawyer-Kenyon proposal of a health unit as one of four main divisions in a department of public welfare, 1919–1921.

9. The plan of the Joint Committee on Reorganization for public health as one of three main divisions in a new department of public welfare as part of a general reorganization scheme, 1923–1925.

10. The plan of W. F. Willoughby for a department of public health as part of general reorganization, 1921–1923.

11. The plan embodied in the Parker bill (the author calls it the "Tobey proposal").

To these eleven serious attempts to make more effective our federal health activities, Professor Leigh adds a pro-

osal of his own. He suggests a new department of education and health. It would comprise the Public Health Service, Children's Bureau, St. Elizabeth's Hospital, and Bureau of Education. There would be an advisory health council and various interdepartmental boards. The divisions of the proposed department are completely set forth and details to or liaison with other federal bureaus, such as Indian office, Bureau of Mines, Women's Bureau, Bureau of Dairy Industry, etc., are provided. It is suggested that this new department also supervise the health activities of the District of Columbia.

This interesting proposal may be an ideal, but on account of many practical difficulties, political and administrative, it will be a long time before it receives serious attention.

Congressional matters to interest physicians—Although the American Medical Association has twice gone on record in favor of the principles of the Parker bill for federal health correlation, this measure is not included in a description in the A.M.A. *Bulletin* for November, 1927, of nine matters of interest to physicians which are likely to come before Congress.

The nine subjects said to be of importance to the medical profession, whose policies regarding them are expressed, include: (1) a proposed measure to insure notice to all interested parties of every regulation proposed by the Commissioner of Prohibition under the narcotic or prohibition laws; (2) a measure for the control of cosmetics in interstate and foreign commerce; (3) deduction by physicians from their income tax returns of traveling expenses incurred in attending professional meetings; (4) an amendment to the national prohibition law, allowing physicians to prescribe as much alcohol as the patient needs (therapeutically and not socially); (5) legislation to secure retirement privileges for

disabled medical officers who served temporarily during the World War; (6) more hospitals for veterans for treatment whether incurred in line of duty or not; (7) a medical practice law for the District of Columbia; (8) further extension of the Maternity and Infancy Act; and (9) anti-vivisection legislation.

The American Medical Association is in favor of the first five measures and the seventh, if they are introduced; but it is opposed to the sixth, eighth, and ninth.

More Arguments Against the Sheppard-Towner Act—Some alleged administrative anomalies of the federal Maternity and Infancy act are pointed out by Dr. W. C. Woodward and J. W. Holloway, Jr., of the Bureau of Legal Medicine of the A.M.A. in the Association's *Bulletin* for November, 1927. They call attention to the fact that the term "infant" legally means any person under 21 years of age, but that, judging from the hearings on the bill before it was passed, the law was intended to embrace only infants under 1 year of age. Then they quote from the plans of 19 states, as approved under the law, which are concerned with older children. Too harsh criticism should not be directed against the federal officers who administer the law, the authors believe, but criticism should rather be directed against the uncertain terms of the act itself.

Reporting on suspicion upheld—

The reporting of actual cases of disease to health officials has frequently been upheld by the courts. Requirements to this effect are proper, and physicians who make the reports in good faith are not liable for damages of any kind. Now comes the decision of a court which upholds the reporting of suspected cases of disease, even though an injury results. In this case, *McGuire v. Amyx*, 297 S.W. 968, decided by the Supreme Court of

Missouri, the facts seem to indicate that the physician made a mistake, but since he acted in good faith, as a reasonable and prudent man would do, there was no liability.

The facts were that a woman went to consult her physician about herself. She was accompanied by her 7-year-old daughter. While examining the mother, the physician noticed a rash on the child and concluded that it indicated or was suspicious of smallpox. He notified the health department and the child was taken in an ambulance to a quarantine hospital, where the chief diagnostician pronounced her as afflicted with smallpox. The child was not sick and during the 9 days she was confined to the hospital played in the yard and with the nurses. Six days after her discharge from the hospital she became sick and developed an unmistakable case of smallpox. The parent as next friend brought suit against the physician, the diagnostician, and the hospital superintendent for \$30,000 damages. He failed to recover in the lower court and this decision was affirmed on appeal, 8 years after the episode occurred. The court stated:

The public health is of the greatest concern to all. By law its keeping rests with the attending physicians, householders, and health officers. Public policy favors the discovery and confinement of persons afflicted with contagious diseases, and we think it not only the privilege, but the duty, of any citizen acting in good faith and on reasonable grounds to report all suspected cases, that examination may be made by experts and the public health thereby protected. We hold this may be done without being subjected to liability for damages.

Although stating no new proposition of law, this is an important decision on the liability of health officials and of physicians in connection with their public health responsibilities. Not only does it hold that a physician is not liable for a mistake in judgment in reporting a suspected case of communicable disease, but also that a health officer who exam-

ines a patient and quarantines him because he has reasonable grounds to believe that the safety of public health requires such action, cannot be held liable merely because it turned out that he was wrong. Even though the patient contracted smallpox as a result of the mistake, there is no liability so long as the health officer did not act wantonly or recklessly.

Whether or not there was actionable negligence in any such set of facts is, of course, a question for the jury to decide. In this case they found for the defendants and the court upheld the decision on points of law advanced against it on appeal.

Child Labor Day—The problem of child labor is not yet solved, according to the National Child Labor Committee, which has sent out an announcement of a Child Labor Day the last week-end of January. The committee says:

Child Labor involves more than the mere question of the age at which a child should be allowed to go to work. It includes the prohibition of all work for children under 14, and of dangerous work for children under 16; it includes the establishment of an 8-hour day and the prohibition of night work for children under 16; and evidence that the child is strong enough for work.

In 14 states the law now carries an exemption which makes it legal for children under 14 to work in factories or canneries, at least out of school hours; in 11 states children are permitted to work 9 to 11 hours a day; in 17 a physician's certificate is not required of a child starting work; in 28 children of 14 may work around explosives; in 22 they may run elevators; in 17 they may oil and clean machinery in motion.

Chicago wins—The State of Wisconsin brought suit in the United States Supreme Court against the State of Illinois and the Sanitary District of Chicago in order to stop the diversion of the waters of Lake Michigan through the

What Can We Do About Measles?*

GEORGE C. RÜHLAND, M. D., FELLOW A. P. H. A.

Director, Syracuse Health Demonstration

and

A. CLEMENT SILVERMAN, M. D.

*Director, Bureau of Communicable Diseases Syracuse Health Department,
Syracuse, N. Y.*

THE ultimate conquest of measles depends no doubt upon the discovery of the specific causal agent and the development of an immunization procedure, similar to that now employed against diphtheria and scarlet fever. Perhaps the dawn of the tomorrow that will bring this achievement is not far distant; certainly the laboratory research worker is busily endeavoring to determine the etiology of this disease.

At present, however, there still seems considerable doubt as to the identity of the specific organism. Whether the green streptococcus of the Tunnickliff ' type will prove to be the real cause, whether it is the green diplococcus of Ferry,² or whether these are merely variant symbionts and the true causal agent is a filtrable virus other than those mentioned, as Park³ suggests and Degkwitz⁴ insists, the future must determine.

In the meantime the health officer faces the fact that measles occurs with distressing regularity of from 2- to 3-year intervals and spreads rapidly in spite of the usual control measures.

A recent survey by the U. S. Public Health Service, based on inquiries made of several thousand university students in different parts of the United States,⁵ shows that approximately 90 per cent of males and 95 per cent of females 20 years of age and over had suffered attacks of measles. This indicates fairly well the still widespread prevalence as

* Read before the Health Officers Section of the American Public Health Association, at the Fifty-sixth Annual Meeting at Cincinnati, O., October 17, 1927.

well as the high incidence of measles. The factors that are responsible and contribute to the usual rapid spread of measles are, of course, well known.

There is the exceptionally high degree of infectiousness of the disease itself, the difficulty of recognizing and so controlling the disease during the prèruptive stage, when infectivity is highest, and the unfortunate popular belief that measles is after all only a negligible disease of childhood with a corresponding indifference and lack of coöperation on part of the public. A sense of hopelessness in the face of these overwhelming adverse odds no doubt is responsible for the general lesser interest that characterizes official activity when dealing with measles.

This attitude on the part of the health officer, Dr. Godfrey¹ maintains, is an additional reason why better progress in the control of measles has not been made so far. Agreeing that with present facilities any attempt to prevent *all* measles is foredoomed to failure, he suggests that action should concentrate on a program to protect especially children under 3 years of age, since after all fully 70 per cent of all measles deaths fall within that age period.

Although Brownlee, in England,² urged a similar program for the protection of child life in the early age group, it appears that nowhere was a consistent effort made to try out such a plan.

An opportunity for such a practical tryout of the plan presented itself to us in Syracuse in the late winter of 1926. A study of the history of measles in Syracuse shows that measles appears there in 3-year intervals. The outbreaks, beginning usually late in February or early in March, run through 2 years, with a summer remission each year, showing a crest of the epidemic wave in May, which then falls rapidly in June. With a record of a measles epidemic in 1923-24, it was therefore a simple matter to forecast the next epidemic for 1926-27. See Chart I.³

PLANS AND PROCEDURES

Knowing that an epidemic of measles was impending, the next step was to plan for action that would secure as much protection as possible for children under 3 years of age. Three things seemed especially important to this end:

1. To arouse the public, especially those families having children in the dangerous age group
2. To secure the coöperation of the medical profession
3. To develop the departmental machinery, i.e., especially the nursing staff

For the first of these steps the press was taken into our confidence. Through the daily papers announcement was made, even in the fall of the year 1925, that according to past experience Syracuse would have

Profile showing periodicity of measles at Syracuse

an epidemic of measles beginning in the late winter or early spring of 1926. It was pointed out that, contrary to common belief, measles, through complications, is a dangerous disease, especially to children under 3 years of age, and to all delicate children. Since it was difficult to recognize measles during the early stages, all children exhibiting any symptoms of a cold should be put to bed, kept separate from other children, and a physician called to pass upon the case. Warnings were also issued against the seriousness of complications which might follow if children were allowed to leave bed too early during the convalescent period.

All cases were to be reported promptly to the Health Department. The medical profession was likewise informed through the department's *Weekly Bulletin* of the impending epidemic, and the use of human convalescent immune serum was urged and offered for children of the dangerous age group. Special pains were taken to impress upon the nurses of the department the high degree of contagiousness of measles, the usual modes of transmission, early symptoms, and—above all—the great necessity of protecting children under 3 years of age and all delicate children.

The importance of discovering all contacts at the earliest possible moment and of segregating them, if possible, and the giving of human convalescent immune serum to every young and delicate contact was also stressed. Detailed information was given on the instruction of families having measles cases. Each nurse was furnished with typewritten copies of these instructions. Families under quarantine were furnished copies of the educational measles folder supplied by the State Department of Health.

The epidemic developed, as predicted, in February, 1926. The public was kept informed as to the progress of the epidemic, with constantly repeated urging to call a physician early and to give special care to the child under 3 years of age and to all delicate children.

The department operated with an average of 21 field nurses during the time of the epidemic. The nurses employed by the Department of Public Instruction (20 in number) gave valuable assistance, bringing the total number of nurses available to a ratio of about 1 to each 4700 of population.

At the beginning of the epidemic, Dr. Godfrey, Director of the Division of Communicable Diseases of the New York State Department of Health, detailed one of his nurses to assist in organizing the home visit work of the nurses. The State Health Department also furnished some human immune serum, though most of the serum used was obtained locally from convalescent patients.

Schools were not closed during the epidemic, nor were infant welfare clinics discontinued. Due to our following a generalized nursing plan, it was possible to devote the greater part of the home visit service of the nurses to the search for measles cases and the instruction of families. It was necessary to hospitalize only 24 cases because of home conditions.

STATISTICAL DATA

In dealing with the statistical facts of the 1926-27 measles epidemic in Syracuse, it should be understood that the efforts of the department centered not in the prevention of all measles but in an attempt to protect child life, especially under 3 years of age, and to lower, if possible, the mortality for that age period.

In Table I is presented the total number of cases and deaths, together with the indicated fatality per 100 cases for the epidemics of 1923-24 and 1926-27 respectively, as well as the number of cases and deaths with their fatality at different age periods.

There were reported for the epidemic of 1923-24 of German measles and measles a total of 4,722 cases with 59 deaths, or a fatality of 1.38 per 100 cases as against 5,317 cases of true measles with 18 deaths, a fatality of 0.34 per 100 cases for the epidemic of 1926-27. This seems a fairly favorable showing—the mortality rate for the 1926-27 epidemic representing a 68 per cent reduction from that of the preceding epidemic. This rate seems especially favorable when it is considered that the total number of cases for the epidemic of 1923-24 includes German measles, whereas the total for the 1926-27 epidemic counts true measles only.

TABLE I

MEASLES CASES REPORTED, DEATHS AND CASE FATALITY PER 100 CASES REPORTED, BY AGE GROUPS
SYRACUSE, 1926-1927

	1923-1924 ¹		1926-1927		Fatality per 100 Cases	
	Cases	Deaths	Cases	Deaths	1923-1924 ¹	1926-1927
ALL AGES	4722	59	5223	18	1.38	0.34
Under 1 year	119	9	164	5	7.56	3.04
1 year	314	21	324	7	6.68	2.16
2 years	423	14	424	2	3.30	0.47
3 years	481	7	534	2	1.45	0.37
4 years	447	1	537	1	0.22	0.18
5 to 9 years	2492	5	2600	1	0.20	0.03
10 years and over	446	2	640	..	0.44	...

1. Figures for 1923-1924 include German measles, but it is probably unlikely that very many cases were reported; for 1924 only 111 cases of German measles were recorded.

It is interesting and significant also to compare the fatality rate of 0.34 of the 1926-27 epidemic with the modal case fatality rate for cities with a population of 100,000 or more, which, according to Sydenstricker, is about 0.6 (based on 15 years of frequencies). This will give Syracuse a rate of 43 per cent under the average for cities in this population group.

The difference in the mortality rate for the two Syracuse epidemics under consideration shows up even more markedly when these rates are considered by age groups. For children under 1 year of age the 1923-24 epidemic shows 119 cases with 9 deaths, giving a fatality rate of 7.6, as against 164 cases with 5 deaths and a fatality rate of 3.0 for the 1926-27 epidemic.

ANALYSIS OF STATISTICS

For *all* cases under 3 years the fatality in the 1923-24 epidemic is 5.1, as compared with a rate of 1.6 for the last epidemic. It appears then that the mortality from measles in Syracuse during the 1926-27 epidemic was 69 per cent lower for the age period under 3 years, compared with the immediately preceding epidemic. The question now arises—May we accept that this improvement in mortality stands in any relation to what was done? This in turn calls for an inquiry into:

1. The nature of the epidemic, i.e., was it milder than the preceding one?
2. Was there any material difference in the proportion of susceptibles or in the age distribution in this group?
3. Are there any tangible factors in what was done that could have brought about improved results?

Nature of Epidemic—So far as the first of these questions is concerned, it is of course impossible to give absolute proof as to the virulence of the epidemic in question. There are no bacteriological standards by means of which the virulence of the contagium of measles, whatever it may be, can be tested. Nor is there clinical evidence unless we accept the impressions of the clinician as to the virulence of the epi-

demic of 1926-27 as compared with the one preceding. We must therefore fall back upon a comparison of mortality figures at Syracuse with those of other nearby cities as the only measurable factor on the basis of which the probable virulence of the 1926-27 measles epidemic may be judged.

Taking for this purpose the statistics of measles in the cities of Rochester and Yonkers, both of which reported epidemics of measles in 1926, we find the following:

	<i>Number of cases</i>	<i>Deaths</i>	<i>Fatality per 100 Cases</i>
Rochester	2437	17	0.70
Yonkers	3782	44	1.16
Syracuse	2714	4	0.16

It is understood, of course, that this represents a comparison for only one year of the epidemic.

The many factors that ordinarily stand as objections in comparing the general mortality of one city with that of another are also fully appreciated. However, notwithstanding all this, it yet seems not unreasonable that the specific mortality for measles in the communities in question should serve as an indicator to the virulence of measles at that time and season and for this section of the country.

TABLE II
MEASLES CASES REPORTED AND PER CENT DISTRIBUTION BY AGES

2. Of these 1 exposure is probable but not definite

are in comparatively close proximity to and in communication with one another. It seems difficult under these circumstances to assume that there should have been any marked variation in the virulence of measles for the respective cities which would not have affected all of them. It may be accepted therefore that the factor of virulence in the 1926 epidemic did not materially vary in favor of Syracuse.

Proportion of Susceptibles—We now examine the next point that could have influenced the mortality; namely, the proportion of susceptibles and the difference in the age distribution for this group. The history of measles for Syracuse shows a rather uniform recurrence of epidemics after about 19 months quiescence. Syracuse is a community of rather steady and average growth. There are no marked fluctuations in the loss or additions to her population. Participation of the number of susceptibles in different age groups in the epidemics has been about the same, so that the factor of an abnormal accumulation of susceptibles cannot be considered as a determining point.

In Table II is shown the number of cases according to age group for the epidemic of 1923-24 and that of 1926-27 and the percentage distribution of cases by age for the two epidemics. It will be seen that this is quite uniform for the two epidemics. Of particular interest is the per cent distribution of cases for the age group under 3 years. In the 1923-24 epidemic this group shows 856 cases, or 18 per cent of all cases reported. The 1926-27 epidemic records 930, or 17 per cent, for this same age group.

Factors bringing results—This brings us to a consideration of the third and most material point; namely, What specific results, if any, were noted in relation to specific methods employed? Is there any

TABLE IV

2. Two of these exposures were probable but not definite.

evidence that the public responded in any way to the educational campaign? It is obviously difficult to answer this question unqualifiedly, especially in such a way that would demonstrate that an improvement in popular interest in the epidemic was noted, since there are no comparable data.

It is nevertheless interesting, and undoubtedly significant, that in an analysis of 726 primary cases of measles during the recent epidemic a physician was called in 653 cases, or nearly 90 per cent, on or before the 4th day of illness. When we consider that a physician is not usually called for what appears to be an uncomplicated cold, such as the symptoms of measles in the præruptive stage, then we are justified in concluding that this record shows a most remarkable response to the health department's educational effort.

The practice to call a physician before the 5th day after the onset of illness was undoubtedly an advantage in treating children in the under 3 years age group with human immune serum.

Tables III and IV give our experience with the use of human immune serum. Out of a total of 155 patients that received serum, 81 did not develop measles, and 74 developed modified measles. Two cases outside this group that received serum on the 9th and 10th day following exposure developed measles with complications, indicating that serum employed so late after exposure is of course useless. There was no measles fatality in the entire group. Of the entire series of 155 cases treated by serum, 112, or 72.2 per cent, were children under 3 years of age. In this group 54, or 48.2 per cent, developed modified measles; and 58, or 51.7 per cent, did not develop it.

SUMMARY

It is of course clear that, with the experience of but a single epidemic, conclusions must be limited and drawn with care. Insufficient data for the preceding epidemic makes comparison for every point impossible. Nevertheless, the following statements seem warranted:

1. The plan of Brownlee and Godfrey, to concentrate on the age group under 3 years for a reduction in the mortality of measles, seems entirely practical, and has in the management of the 1926-27 epidemic at Syracuse apparently yielded substantial reduction in the mortality of children under 3 years of age.
2. The plan can be most effectively carried out under a generalized nursing system.
3. Useful public interest and coöperation in such a plan can be stimulated and sustained to a remarkable degree by proper publicity.
4. The plan does not require new methods, but merely calls for an intensified application of known procedures.

The Eleventh Annual Roll Call

SIX hundred and forty-three thousand dollars for 20 disasters abroad, \$8,216,893 to relieve 690,000 people as a result of 77 domestic disasters! These are the figures given in the report of the last fiscal year of the American Red Cross.

At the time of the Mississippi Flood, many of those who watched their property being destroyed, or who suffered even greater losses which could not be redeemed by money, learned for the first time the meaning of Red Cross Disaster Relief.

The national and international program of the Red Cross is ever increasing. There are more demands for service and the Red Cross must act in the name of the people of the United States. Is it not fitting, therefore, that the Red Cross should look to the people for the support which larger membership gives? These are the reasons for membership drives:

1. That the files of enrollment in the nursing service may be kept up to date and ready for instant service
2. That disaster equipment may be constantly in readiness
3. That the public health nursing program may be kept going
4. That the teaching of home hygiene and other educational activities may be continued

"Forty-five thousand enrolled Red Cross nurses should be able to influence many times that number of persons to join and thus to participate in the work of the greatest humanitarian agency in the world." In its effort to secure 5,000,000 members the Red Cross offers a challenge to the national pride, conscience and spirit of the American people.

The Preparation and Presentation of Papers*

MAZŸCK P. RAVENEL, M. D., FELLOW A. P. H. A.

University of Missouri, Columbia, Mo.

THE FIRST requisite for a paper is having something to say which is of value. Many editors demand that the matter presented shall be original or given from a new viewpoint—a good rule, though many valuable papers consist of a review of what has been presented by others with conclusions which bring order out of chaos and give to the average reader a clear idea of existing knowledge.

All editors are pestered by authors who present potboilers, which are usually papers on something new which is proposed, or old material worked over in slightly different form. In medicine this is particularly the case, but less so in the class of papers presented at meetings like that of the American Public Health Association or to such journals as its official organ.

The subject having been selected, the presentation should be made as clearly and briefly as possible. Long historical reviews are generally out of place, though a certain amount of history will often tend to clarify what the author has to present. Quite recently it has been the practice to give long bibliographies, but most journals have taken a stand against this, since in many cases it has been perfectly evident that the authors had never read the articles, but had copied lists given by other writers, who in turn had copied from their predecessors. It was a common thing to find errors passed down through a long series of writers.

The title should be descriptive, but not an abstract of the matter presented. Ambiguous and nondescriptive titles may deprive an author of the satisfaction of being quoted, since the reviewer of literature is misled. Too many papers are built on the plan of the Negro preacher for his sermons: "First, I takes a text, then I tells 'em what I is going to tell 'em; then I tells 'em what I wants to tell 'em; then I tells 'em what I has done told 'em." A certain amount of repetition may be useful, but in general it should be avoided.

* Read before the Joint Session of the Health Officers and Public Health Education Sections of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

Subheads and conclusions are useful, but the latter should be strictly in accordance with the evidence presented. Note this extract from a recent English review of an article by an American: "The reviewer would enter a mild protest at the growing habit of recording conclusions which bear little obvious relation to the data set out in the body of a paper; particularly when, as in this case, the actual heading of the final section is 'Summary and Conclusions.' "

Quotations should be correct and brief. The average reader of scientific journals is probably as conversant with literature as the average writer. A reference with perhaps a short quotation is generally all that is needed. No article should be essentially a reprint of material by other writers.

Good style is hard to acquire and some writers never master it. Everyone knows that certain articles are read with pleasure while others, which may contain better material, are exhausting. Good associations in early life are almost essential for good writing and good speech, but much can be accomplished by study, reading and practice. A good writer is never lazy about consulting the dictionary. Style manuals, such as those put out by the Government Printing Office and publishing houses, and desk books, should be in the hands of every writer. The advice to "write and rewrite, rewrite again and then revise" is good. Sir Clifford Allbutt was a master of English, and no one would have suspected that he felt obliged to give a great deal of care to his articles; yet he tells us that he made at least four drafts of a manuscript. After making a rough draft from notes, a revision resulted in the cutting out of unnecessary words, phrases, sentences and paragraphs, by which he reduced the length from 20 to 25 per cent. He then recast sentences and paragraphs which seemed ambiguous, and gave particular attention to the choice of words fitted to convey the exact meaning intended. The manuscript was laid aside and some weeks later the final revision made. In America, the late Sir William Osler stood easily first among scientific men in his command of English, both in speaking and writing; yet it is known that he often made a first draft in long hand from notes, and as many as three others on the typewriter, the last of which was submitted to the printer. With such examples, the average man should certainly not expect to turn out a finished article in one sitting.

English is a rich language, if a difficult one. The correct word can always be found. Coining new words and giving new meanings to old words should be avoided.

A few examples of poor diction will suffice: The use of "case" instead of patient; Schick used as a verb, as "I Schicked him"; "I operated Mr. Smith." The verb "operate" means "to work." Does the sur-

geon unwittingly tell us that he "worked" Mr. Smith when he operated on him? From a noted clinic we have "The lines of divergence are converging"—a contortion equalled only by the advice given by a clergyman to his congregation: "Stop, turn round, and look yourselves square in the face." Boston contributes the following: "The principle of 'hormone' activity was studied subsequently by Bayliss and Starling alone, and both workers . . ."; "For a pittance by no means slight"; "He developed glands of the throat." . . . "Study in Vienna, Berlin, Strassburg and other trans-Atlantic foci."

Examples could be multiplied indefinitely, as everyone who has a rudimentary knowledge of English and who reads literature with a modicum of care knows.

PRESENTATION OF PAPERS

Not everyone has the gift of language, and many can never become forceful speakers; but all can follow certain elementary principles and give a clear presentation of ideas if their ideas are clear to themselves. At every meeting of this Association, as well as others, the audience is punished by speakers who have no consideration for their hearers and no appreciation of the lapse of time. Enthusiasm is a good trait, but carried to excess is very trying. Many of us can recall a paper which consumed an hour and twenty minutes; another, by a distinguished guest, almost as long, whose manuscript resembled Joseph's coat of many colors; lantern slides and charts poorly made and largely illegible, though essential to the presentation. Speakers will do well to remember the reply of the bishop to the curate who asked if forty-five minutes was too long for a sermon. The bishop answered that he would not care to lay down a hard and fast rule, but his experience led him to believe that the majority of souls were saved during the first fifteen minutes. Great discoveries and matters of exceptional importance sometimes deserve a longer time for presentation, but it is always well to stop while the audience is eager for one to continue.

The most effective speakers are often those who prepare their material, familiarize themselves thoroughly with it and speak from notes, in order to follow the chosen sequence, and to avoid digressions and the use of more than the time allotted. A common mistake is to interrupt the reading of a paper by making side remarks and giving illustrations. Some can do this gracefully, but the great majority annoy their audience, break the force of what they have written and lose the thread of their argument.

If one has originality and histrionic talent, the stereotyped methods may sometimes be abandoned with advantage. We recall the pleasure

given last year by a speaker who acted a dual rôle in an alleged argument over ventilation. What is more to the point, he put it across more effectively than could have been done by an hour of the usual dry-as-dust discussion.

If time is limited, as it should be and generally is, precious minutes must not be wasted in bemoaning the fact or telling how much more information could be given "if time allowed." Apologies for lack of ability or unpreparedness are generally out of place, often insincere and always tiresome. "Mock modesty is the worst form of pomposity."

THE EDITOR

The editor deserves some consideration, though writers should realize that the publication of their articles will be greatly facilitated by furnishing properly prepared manuscripts. We can hardly expect every contributor to know all the rules adopted for various publications, in order to obtain uniformity of type, capitalization, paragraphing, etc. These may be left to the editor, but he should have a clear manuscript, correctly spelled, typewritten, double spaced, and on one side of the paper only. One of the worst sins of writers is the misspelling of proper names, though all poor spelling is inexcusable. Especial care is necessary in giving correct references, which should be indicated by numbers in the body of the paper.

There is great lack of uniformity in abbreviations for references. We recommend the list of publications with the proper abbreviations given in *The Art and Practice of Medical Writing*. Titles of books and articles should not be abbreviated.

In America the standard size of manuscript paper averages 8½ by 11 inches. This size is adapted to ordinary typewriters, to linotype machines and to filing cases. There is little excuse for using odd sizes. There should be wide margins with plenty of room left at the top and bottom of the pages. Compliance with these rules facilitates publication and lessens the cost to the journal and often to the writer, since fewer corrections need be made.

THE REMEDY

With all compassion for the difficulties of program committees, we believe that they are often responsible for the poor papers presented. It has been suggested that each section should look over the list of those who have had places on the program during the past few years, including chairmen; pick out two or three whose papers were notably poor in substance or were badly presented, or who have persistently violated the rules; and refuse to let them read papers at the next meeting. The

papers could still be offered to the journal and published or not according to the judgment of the editors.

Certainly such action would put prospective authors and speakers on their mettle, and might induce them to follow the last piece of advice which this paper will give—to study one or more of the following books:

Joint Report of Voluntary Agencies and Medical Profession

AN agreement on methods of coöperation has been reached between organized voluntary health agencies and the medical profession in New York State. Their joint report was accepted by unanimous consent of the House of Delegates of the State Medical Society and the Board of Managers of the State Charities Aid Association.

The joint report is regarded as significant in that it promises more "harmonious and effective development of public health in New York State." It is hoped that through this movement similar agreements may be reached in other states.

A resumé of the things agreed to by each county medical society and the voluntary health agencies is as follows:

1. To appoint members of the county medical society to serve as members ex-officio on the board of directors or the executive board of the voluntary health agencies.
2. To study and consider any program activities of any voluntary health agency for information and suggestion.
3. To appoint a special committee on public relations to confer with committees of the voluntary health agencies on matters of mutual interest.
4. To report to the State Medical Society any matter upon which no decision can be reached with the voluntary health agency, in the hope that some satisfactory settlement can be reached.

The voluntary health agencies also agree to conduct at least one open meeting annually.

The State Medical Society was represented on the Joint Committee by Dr. G. W. Cottis of Jamestown, Chairman; Dr. Wilbur G. Fish, Ithaca; Dr. W. Warren Britt, Tonawanda; Dr. Thomas P. Farmer, Syracuse; Dr. Terry N. Townsend, New York City. Dr. George M. Fisher, then President, and Dr. Joseph S. Lawrence, Executive Officer, were members ex-officio.

The representatives of the State Charities Aid Association were Dr. Livingston Farrand of Ithaca, Chairman; Homer Folks, Yonkers; John A. Kingsbury, Yonkers; Dr. H. G. Weiskotten, Syracuse, and Dr. Linsly R. Williams, New York. George F. Canfield, President, and George J. Nelbach, Executive Secretary of the State Committee on Tuberculosis and Public Health, were members ex-officio.

Recent Health Observations in the Mississippi Flood Area*

WILLIAM DE KLEINE, M. D., FELLOW A. P. H. A.

Director, Child Health Demonstration, Salem, Ore.

THE Mississippi flood in the spring of 1927 was the largest and most devastating disaster of record in the United States. The Florida tornado in 1926 was the next largest, crippling seriously more than 24,000 families. The Mississippi flood made more than 600,000 individuals temporarily destitute. The homes of more than 750,000 people were flooded, and many completely destroyed or badly damaged.

While smaller floods in the Mississippi Basin occur nearly every spring, the 1927 flood surpassed all others. Ninety-two counties and parishes in 6 states (Kentucky, Missouri, Arkansas, Tennessee, Missis-

*Read before the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

NOTE. Dr. DeKleine was loaned to the American Red Cross and served as Acting Medical Director in August and September, during the illness of Dr. W. R. Redden. He spent most of this time in the flood district, which gave him an excellent opportunity to observe health conditions.

ssippi, and Louisiana) were either wholly or partially inundated for from 3 to 8 weeks, and in some instances for a longer period. The levees and river embankments of the Mississippi and its tributaries were broken in more than 200 places, submerging more than 20,000 square miles. The number of deaths from accidental drowning was, however, comparatively low—estimated at about 250.

The Red Cross was quick to recognize that it was facing not only an immense relief problem, but also a staggering public health problem such as had never been experienced in the United States in peace time. More than 100 refugee camps and relief stations were opened. The Red Cross fed, clothed, sheltered, and provided medical and nursing care for several weeks for more than 600,000 people, and rehabilitated their homes and properties after the flood had receded. More than 50,000 will be fed and clothed continually until the spring of 1928.

Wherever local hospitals were unable to cope with the situation, temporary hospital facilities were provided for communicable diseases, for the usual run of illness, maternity service and care of the new-born. A fund of more than \$17,000,000 was contributed to meet all these needs.

The concentration of so many people in refugee camps necessitated the closest supervision and regulation of camp life in order to avoid outbreaks of smallpox, typhoid fever, and other communicable diseases. The very crude condition of some of these camps made this problem all

In perhaps the most far reaching disease prevention program this country has ever seen in peace times, the Red Cross inoculated against typhoid fever nearly 410,000 persons and vaccinated against smallpox 183,000 in the 7 states affected by the Mississippi Valley flood. The doctor in this picture is vaccinating against smallpox in a Louisiana refugee camp.

the more difficult. The inundation of so large a territory with highly polluted water presented the possibility of contaminating many of the public and private water supplies, and, indirectly, many food supplies. It was therefore urgent that drastic steps be taken immediately to prevent typhoid and other intestinal infections, and epidemics of the ordinary communicable diseases.

CONFERENCE TO ORGANIZE FLOOD AREA

It was recognized early that the state and local health authorities were not prepared to cope adequately with this staggering problem because of the lack of funds. Immediate steps were therefore taken, with their approval, to organize the entire flood area for public health control. A conference was called in Memphis, on April 28, at the instigation of W. R. Redden, M. D. Medical Director of the Red Cross. To this conference were invited the state health officers, representatives of the U. S. Public Health Service, the Army and Navy, state medical societies, the American Medical Association, and others to discuss this situation and to put in motion the necessary machinery for adequate public health control. The U. S. Public Health Service immediately assigned Senior Surgeon John McMullen to the Red Cross Headquarters as liaison officers to coöperate in bringing such assistance to the local health authorities as seemed most desirable.

The public health work was, however, directed and conducted entirely by the state and local health departments. The Red Cross Medical Service acted as a clearing house to furnish supplies and personnel when requested. The nursing service in the field and in the refugee camps was directed by Elizabeth Fox, R. N., and Malinde Havey, R. N., Directors of the Red Cross Public Health Nursing Service. The staff nurses who served in the field and in the camps carried a large share of the disagreeable burdens and inconveniences that always accompany strenuous duties of this character. Local physicians, health officials, army medical officers, and volunteers from other communities and states carried the burden of the medical and public health services. Twenty-two states responded to an appeal for experienced personnel by sending physicians, nurses, sanitary officers, and other public health workers. Three hundred and twenty-nine nurses volunteered. One man came armed with a shot gun and offered his services for sanitary duty.

The U. S. Public Health Service furnished experienced personnel who were attached to the offices of the state health departments to help direct their work. This agency, in coöperation with the Rockefeller Foundation, also helped finance a program of organizing permanent

county health units, as will be described later. The Red Cross, however, is deserving of the credit of instigating and correlating the medical, nursing, and public health activities.

The correlation and direction of all these numerous agencies and activities, in which all these organizations participated, represent, we believe, an outstanding achievement and triumph in emergency public health administration. There was practically no overlapping nor duplication of effort, and there existed a minimum amount of friction and misunderstanding. It was a splendid example of effective team-work.

More than half a million individuals were immunized against typhoid fever, and about 200,000 against smallpox. More than 200,000 gallons of oil were used for mosquito control. Large quantities of quinine sulphate, estimated at 2 tons, were distributed and used for the prevention and treatment of malaria. With the exception of typhoid vaccines, the supplies were furnished almost entirely by the Red Cross.

The Red Cross also financed an extensive screening program. Under the direction of J. A. Le Prince, of the U. S. Public Health Service, more than 22,700 screen doors were constructed and installed, and more than 25,000 windows were screened. It was intended that all homes of malaria carriers should be carefully screened. This was done wherever possible, although the work was not entirely confined to that. Many houses were screened in localities where they could serve as valuable object lessons. This screening program had perhaps even greater value as an educational measure than as a means for the immediate control of malaria.

The organization of medical and nursing service and hospital facilities; the immunization program; the prompt isolation and quarantine of patients; the adoption of adequate sanitary and public health measures in the refugee camps; the supervision of food supplies in the camps; the screening program and other public health measures were no doubt responsible in a large measure for the excellent health conditions that were maintained. According to the records of the state health departments, the incidence of typhoid fever, diarrheal diseases in infants, smallpox, malaria, and certain other communicable diseases was materially lower in the flood area during the period following the flood than it has been during similar periods in the last 5 years. The figures as given by the state health commissioner of Louisiana are a fair example of what they are in other states. From January 1 to August 26, 1927, 142 deaths from typhoid were reported, as compared with an average of 463 for the same period for the last 5 years. One hundred and ninety-eight cases of smallpox were reported in 1927, as compared with an average of 713.4 for the same period in the last 5 years.

This little fellow had more exciting experiences in a week than many persons have in a life time. Rescued from the second story of his home, and carried in a small boat over the great "Father of Waters" to a Red Cross camp, he is in this picture receiving first aid treatment for his injured arm at the emergency hospital in the Vicksburg, Miss., refugee center.

This, we believe, is a triumph for public health and preventive medicine. It indicates that the incidence of communicable diseases and other illness and subsequent death rates can be controlled and materially reduced in the emergencies of peace time as well as in time of war. Secretary Hoover has designated it as a "triumph for public health and scientific medicine."

Pellagra has been a consistent problem of the South for many years. There has been a gradual increase in the incidence of this disease for the last four or five years. Dr. Joseph Goldberger, of the U. S. Public Health Service, made a survey of the flood area during July. In his report to the Surgeon General, he estimated that there were from 45,000 to 50,000 cases of pellagra in this district at the time of the survey, which is considerably more than usual. He attributes this increase largely to economic conditions. The history of the disease indicates very clearly that wherever economic conditions become stringent, the incidence of pellagra increases. Pellagra is confined largely to the cotton belt. With the exception of 1927, the cotton crop has not been very profitable for the past four or five years. This may account for impoverished rations and a subsequent increase of the disease. Whether the flood influenced it materially is not clear. It probably did to some ex-

tent; but the increase is not confined entirely to the flood area. There is a similar increase in other sections of the South, although perhaps not quite so great.

Pellagra results from the absence of certain food essentials in the diet. Dr. Goldberger has shown this conclusively both by animal experimentation and by careful regulation and observation of the dietary of patients in certain state institutions. He designates this food factor as the pellagra preventing, or P. P., factor, and indicates that it is, more or less, always associated with vitamin B. Foods containing vitamin B generally also contain the P. P. factor. Such foods as milk, lean meats, eggs, and certain vegetables have both factors. Yeast in concentrated form is well supplied with the P. P. factor, and is therefore also a valuable aid or remedy for the control of this disease. It should, however, be understood that yeast cannot serve as a substitute for food, but only as a temporary relief measure for treating and controlling the disease.

Upon the advice of Dr. Goldberger, and with the approval and cooperation of the state health officers, the Red Cross undertook to distribute a pure culture of brewer's yeast in powdered form for the purpose stated. This work was started about August 15, and is still in progress. The yeast was shipped to the local health agencies, and was made available to physicians and all public health workers. This is probably the first time a concentrated form of yeast has been extensively used in the United States as a public health measure. It has previously been used by research students and by a few physicians in private practice. At the present writing, more than 5 tons have been distributed in the flood area. We hope to be able to collect sufficient data later through the state health departments that will indicate its value as a public health measure in the control of pellagra. This report will be published at a later date.*

Anthrax in mules and cattle was a problem in certain sections. In a few localities, the disease became a serious problem. The writer was informed by one plantation owner that he had lost 75 mules, and he estimated there had been 1,500 deaths in mules and cattle from this disease in his county. The Red Cross furnished anthrax vaccine to state veterinarians, with instructions to use it freely wherever indicated. This problem, however, was not an extensive one.

The Rockefeller Foundation and the U. S. Public Health Service were quick to recognize an opportunity to develop permanent health units in the counties of the flood area. Through a carefully coördinated plan of procedure between these agencies and the state health de-

* Those who are interested in a study of pellagra and the use of foods and yeast for its control are referred to Dr. Goldberger's reprints published by the U. S. Public Health Service.

partments, this work was undertaken in the flood counties of the 6 states mentioned, after the flood had receded. It will be financed for a limited period jointly by these organizations, with the Rockefeller Foundation and the U. S. Public Health Service assuming the major share of the burden. Wherever the local communities are willing to meet their share of the health budget, the units will be established. They have been successful in organizing full-time health units in all of the flood counties in Kentucky, Missouri, Tennessee, Mississippi, and in the majority of counties in Arkansas and Louisiana.

In order to facilitate this work and to insure the employment of competent help, the Foundation also established a training center in Indianola, Sunflower Co., Miss. This training center also functions as the health department for Sunflower County. The director of the center acts in the capacity of health officer for the county unit. The training consists of a short period of instruction and observation in field duties, thus preparing the students for a more practical approach to their work. On October 1, 23 physicians, 23 nurses, and 37 sanitary officers had completed their training and were returned to the communities or states which sent them. This number has no doubt increased considerably since that time.

The Red Cross and all the other health agencies mentioned have rendered a very valuable service for the health of the entire flood area. Contrary to a general impression prevailing throughout the country, the health conditions of this district have been unusually good during the past summer. It will stand as a lasting monument to public health administration and health service. The damage wrought by the disaster has been offset to a large extent by the saving of life and the prevention of illness. The physicians, the health agencies, and the public have had a practical object lesson in health administration and supervision which should leave a lasting impression and should serve as a great stimulus for the progress of public health throughout the nation.

On the levee at Arkansas City, Ark., this Red Cross nurse vaccinated hundreds of inhabitants of the tent colony there against smallpox and immunized them against typhoid fever. These preventive measures are said to be chiefly responsible for the fact that there was no serious epidemic during the entire disaster.

DISCUSSION

Oscar Dowling, M. D., New Orleans, La.—Louisiana was harder hit by the flood than any other state involved. We had the water from the extreme northern part of the state and the extreme southern part of the state, extending more than 80 miles from east to west at the widest point. More than 700,000 people of our state were affected by this flood in one way or another. About 300,000 were driven from their homes. The statement of Dr. De Kleine was correct, I think, with reference to disease in Louisiana, with the exception that our records show we have not had any increase in pellagra as compared with the last 5 years. Whether we are going to have more remains to be seen. We are greatly indebted to the Red Cross, the Public Health Service, the International Health Board and state and city departments of health at various points in the United States, for valuable assistance in combating disease and in protecting the health and lives of our people.

We were fortunate in having ex-Governor Parker in charge of the work as the personal representative of Mr. Hoover and he started with the motto, "Not one life shall be lost." Three people were on the Texas-Pacific bridge when it was washed away; 2 of them were saved and 1 was drowned. Afterwards, when the refugees were beginning to return to their homes, a boat was capsized one day by people becoming excited and running to one side. This was not charged to the flood because we did not feel it should be charged that way. Therefore, our records show the remarkable results of only 1 life lost that could be charged directly to the flood.

I am happy to tell you that with the help we received from the outside and the work of our own people—because they all coöperated generously and unanimously with us—we came out of the disaster with better health than we had before which of course was most gratifying indeed. This was due we believe to the large numbers of people who were vaccinated against smallpox and immunized against typhoid, together with the service rendered in the camps, the food supplied, etc.

The flood waters first reached us the latter part of April and were with us until August. However, the state is now practically clear of the flood. The loss in financial and physical suffering no one can realize who did not see and go through it.

A. T. McCormack, M. D., Louisville, Ky.—It seems to me that this great session should not close without correlating these messages which have come to us and which are of the utmost importance to every single one of us and to the people we represent.

The emergency of a great disaster found us as unprepared from a scientific standpoint to solve its problems as we were when the World War came and the draft army was first assembled. We know that many of our boys were uselessly and needlessly destroyed because we had not prepared in advance for the solution of the problems that were then presented to the world. In the same way the Red Cross had to mobilize under its powerful influence, and with the very remarkable guidance of Secretary Hoover, the health agencies of the country, and a plan had to be worked out in the face of the disaster instead of having it all prepared in advance.

We had in a sort-of way, before the World War, prepared through the militia a second line of defence. The present problem will be met and solved if we take the combination of the papers presented, make practical their lesson in regard to permanent organization, profit by Dr. Bishop's message showing the remarkable manner in which records can be made to talk for themselves and be made standardized for all rural health departments, with the final summing up of the remarkable ac-

complishments of all of the agencies concerned when they were finally mobilized and gathered together in the flood area under the general supervision and stimulation of the Red Cross in this recent disaster. But for the future are we not going to take the lesson and learn from this emergency the necessity for having in every county in these United States a health organization, ready and prepared, around which can be mobilized those with like training and experience in other similar units over the country, so that in case of any particular disaster at any time, we can mobilize the whole health agencies of the country and focus them on the particular problem which demands solution? It can be done at the saving of millions of dollars. It can be done, as has been demonstrated here, in saving dozens, and frequently thousands of lives in each particular emergency. It seems to me that the important contribution of this whole major flood disaster was the New Orleans Conference (under the leadership of Dr. Redden of the Red Cross, Dr. Ferrell of the Rockefeller Foundation, the distinguished Surgeon General of the U. S. Public Health Service, and all the agencies involved where it was seen that this problem)—where the whole foundation of life in this vast area had been destroyed, where the possibility of healthy life had been interrupted—that these agencies were to gather together and over a period of 18 months conduct a restoration program that would enable people to live healthy lives in that fertile section again.

Are we merely going to restore the *status quo* in this vast area or are we going to demonstrate in these particular counties, through the remarkable work following this emergency, the necessity for such a foundation in every county in the United States and in the world? Whether this be done, as in the South, through the purely local control and local self-government in which we believe, or whether, as in the stronger and more centralized eastern states, through the district system that gets the power from above and proceeds downward, is not a matter of importance; but that in every district, every county, every government in the United States there shall be a permanent organization which shall be ready to carry on every day, not only during an emergency, is most important.

Because of the remarkable demonstration in the flood area in Kentucky, with a population of about 146,000 involved we were able, through the activity of our nurses and our health officers and through the mobilization of senior medical students of the University of Louisville, to inoculate against typhoid fever 75 per cent of the inhabitants in that area. And we have had less than 10 per cent of the typhoid fever which we had in any year in the past 10 years. Now this demonstration during the flood time when all the water was polluted, is the sort of thing that ought to sell the whole public health movement to the people of the other sections which have not yet had a flood. Do they want to wait until they have a disaster before they prepare? Would they want to wait until they have a fire to get a fire department?—or wait until they have a murder, a revolution and robberies and all the other violations of the law before they organize a police department? It seems to me it is just as important at this time that we make the people of the United States understand that a health department, properly organized and properly financed, with trained personnel, is just as essential to the future happiness and welfare of this country of ours as are our courts, our legislative bodies and any other portions of our civil government. That to my mind is the great lesson, the great end-result to be drawn from these three very remarkable papers that we have had the privilege of listening to here this morning.

Relief Measures During and Following the Mississippi Valley Flood*

J. H. O'NEILL

Sanitary Engineer, State Board of Health, New Orleans, La.

THE RECENT flood was, as all such floods are, a combination of synchronized events. A heavily flooded Ohio was met lower down by flood flows in the Arkansas and the White. These were due to rains in the corner of Oklahoma, Missouri, and Arkansas just at a time to bring the rivers draining that territory in concurrent flood with the Mississippi at their mouths.

A flood stage was reached in the Ohio River in March, and from that time on, with heavy rains in the various tributary valleys, the situation became more serious, and it soon became apparent that the valley was faced with the greatest high water fight in its history. The first break occurred at Walnut Bend, 278 miles below Cairo, on April 15; this was followed the next day by a break at Dorena, near New Madrid. Breaks occurred at 5 more localities in April, including a break on the west bank, about 40 miles below New Orleans, caused by a steamship running into the levee. The most serious of these was on April 21, at Stopps Landing on the east bank, about 20 miles north of Greenville, Miss., a city of 12,000 population.

Breaks occurred at 7 places in May, including the break on the east bank, about 15 miles below New Orleans, which was made purposely with a view to protect New Orleans by reducing flood heights at that city. These various breaks resulted in the flooding or partial flooding of 120 counties in 7 states and in driving 700,000 people from their homes. Nearly 600,000 of these were taken care of in 149 refugee camps. Others had issued to them rations and supplies. Three million, eight hundred thousand acres of agricultural lands were flooded.

This very brief history of the flood itself is offered as an introduction to a discussion of the main theme of the paper. It may give some idea of the duration of the fight. It cannot give more than a mere hint of its magnitude; of the length and strength of the battle line; of the constant and nerve straining vigilance to detect promptly such danger

*Read before the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

points as sand boils and bank caving; the almost superhuman efforts to strengthen defenses by raising low levees, by repairing the effects of wave wash and meeting in other ways the grim, relentless, and at times, irresistible attack of the Mississippi; nor of the really wonderful coördination of the work of the various agencies engaged in rescue; of the work of the National Guard troops, American Legion, and Texas cowboys in evacuating people and live stock from threatened areas; of the rescue fleet with its thousands of units varying from skiff and pirogue to surf boats, coast guard cutters and old paddle wheel river steamers; of the thrilling dashes through the roaring waters of a crevasse as a preliminary to a voyage over fields of cane, cotton, or corn, to collect a human cargo from house tops and trees; of the aviators who made aerial surveys to collect information for the guidance of the General Staff, located refugees for the rescue fleet, or carried physicians, nurses, drugs and vaccines to groups isolated by the turbid waters.

Stories of these are in themselves epics which will be told and retold for a long time to come. They will tell of heroic self sacrifice, of dogged courage in the face of overwhelming odds, of brilliant daring, of grim tragedy, of pathos and even of flashes of humor, but can only here be mentioned as a suggestion of a background for the problems of health and sanitation.

On April 22, an advisory committee of members of the Cabinet was appointed by President Coolidge, as President of the American Red Cross, in order to coördinate fully the resources and facilities of the government with the relief operations of the Red Cross. This committee included Secretary of the Treasury Mellon, Secretary of Commerce Hoover, Secretary of War Davis, and Secretary of the Navy Wilbur. This group met with representatives of the Coast Guard, the U. S. Public Health Service and the American Red Cross. A special committee of the Red Cross for the Mississippi Valley Flood Disaster, was established with Secretary Hoover as chairman. The purpose of this committee was, as expressed by Mr. Hoover, "to coördinate the activities of the War, Navy, Treasury and Commerce Departments into support of the Red Cross, which it was determined must continue the primary responsibility for the organization and administration of the relief measures to be taken."

Government agencies had been coöperating as in the past, but this marks the first time that government efforts were placed under the direction of the Red Cross. The efficiency and effectiveness of the relief work under this plan proved its value.

Headquarters for the conduct of all relief operations were promptly

established at Memphis. On April 28 a conference was held at Memphis to consider a program for health and medical service during the flood and for the coördination of the various agencies interested. There were present state health officers and sanitary engineers of states in the flood area; and representatives of the Medical Department of the U. S. Army, U. S. Public Health Service, American Medical Association, 7 state medical societies, and the American Red Cross Medical and Nursing Services.

The conference developed, and by a series of resolutions agreed upon the following program:

Need in any community for nurses, doctors, sanitary engineers, bacteriologists, epidemiologists, and other individuals should be made known to the state health officer, cleared through him and, when he might be unable to meet the request, he would clear for action with the Medical Director of the Red Cross.

Area Directors of the Red Cross faced with an emergency situation might clear direct with the Medical Director of the Red Cross who would then notify the state department of health of the action taken.

All personnel should be released through the same channels through which they came.

The system for obtaining needed supplies should be the same as that for personnel.

The general program of immunization should be restricted to typhoid and small-pox.

Where a case of diphtheria developed, immunization should be restricted to "contacts."

The determination of individuals to be inoculated should rest in the hands of the officer in charge and be limited as far as possible to actual contacts.

The same procedure should be followed with regard to the isolation and, when possible, the immunization in regard to all contagious diseases.

Each state health department should handle its own problem in matter of rabies.

The water in refugee camps should be chlorinated and water in private supplies recommended to be chlorinated, or boiled for thirty minutes where chlorination was impossible.

Where the milk supply did not comply with the minimum requirements of the Public Health Service, the milk was to be boiled. It was recommended that dried milk be used, where an adequate supply of fresh milk was lacking.

The extent and frequency of inspection should be determined by the state health officer in the state concerned.

The set-up of a refugee camp should be: physicians in command and necessary assistants and nurses; sanitary engineer, and supply officer; facilities for isolation; and dispensary and emergency hospital when there were no existing facilities.

Provision should be made for the proper disposition of sewage.

Garbage should be disposed of daily by scavenger service.

Adequate bathing and laundry facilities should be provided in the refugee camps.

All places where food was prepared were to be screened and under the supervision of the medical officer.

Food handlers had to meet requirements of the state health department.

The problem of mosquito control—involving malaria—is a problem which should be handled by the sanitary engineer, with whatever assistance he might need.

Chloride of lime and lime should be the general disinfectants used.

It was considered that hookworm and tuberculosis did not constitute an emergency problem at the time.

In effect this program put the responsibility for the protection of the health of the refugees and the sanitation of the camps and flooded areas where it belonged, on the state board of health, and offered to the state boards of health the resources of the American Red Cross, and through the Red Cross the resources of the U. S. Public Health Service and the trained personnel of other states, who volunteered to help in the emergency.

Fortunately most of the camps could be located where water from satisfactory city supplies could be made available. In some instances water was brought to camps in tank cars from neighboring cities. In others, chlorination of supplies by the use of chloride of lime was carried out under the direction of representatives of the health department.

Few of the camps had sewerage systems but multiple seat flyproof pit latrines provided a satisfactory substitute. Constant policing, however, was necessary to maintain cleanly and flyproof conditions. Many of the camps were electrically lighted and provided with showers baths and places for washing clothes. Kitchens and mess halls were screened.

Vaccination for smallpox and typhoid fever prevention was general. In very few instances was any opposition to this measure shown. Most of the people seemed to realize and appreciate the value of this method of protection. Isolation camps were provided and field hospitals were erected for minor surgical cases.

The small, and usually temporary encampments on the levee or on mounds offered the greatest difficulty. In some instances physicians, engineers, or sanitary inspectors were carried to these areas by airplane. They carried in a knapsack, emergency equipment and supplies, including medicines, dressings, vaccines, and chloride of lime for the treatment of water supplies. In Louisiana a laboratory boat used in shellfish control was assigned to flood duty and made a serviceable mobile unit.

At the camps opportunity was taken to do educational work on various lines. Talks were given on sanitation, mosquito control, personal hygiene, etc., illustrated, where possible, by lantern slides and moving pictures. Classes were held in child hygiene and welfare work.

Except for a few outbreaks of measles and mumps, the health records at the camps have been excellent. The health conditions in the area, as far as morbidity is concerned, were on the whole better than in normal periods.

Part of the problem included the maintenance and protection of water supplies and sewerage systems of communities threatened by the flood or affected only to a point which did not require evacuation of the town. Levees were built around water plants, or doors and windows were barricaded. Emergency power lines were run in. Extra pumps were installed to take care of leakage. This equipment comprised centrifugal pumps, with electric motor, or belt driven from tractor or truck; contractor's sump pumps with gasoline motor; or whatever might be available. Through the generosity of the manufacturers, chlorinators were loaned to state boards of health and many supplies were protected in this manner. In a few instances, where only a part of the town was flooded, or where the water was not deep enough to cause the people to leave, sewer pump motors were jacked up above flood level, shafts extended, and operations continued until the flood was over.

Following the receding of the flood waters, an organization of nearly 100 physicians, nurses, engineers, and inspectors was developed to sanitize the area. This organization included many volunteers from boards of health of states outside the Mississippi Valley.

Efforts were made to complete vaccinations of all who might have missed this treatment at the camps. Cases of diseases were investigated and measures taken to prevent spread of infection. An intensive campaign to promote the building of sanitary privies was undertaken, with really good results. Training was given local men employed temporarily as sanitary inspectors. Engineering advice was given local officials in the rehabilitation of water supply and sewerage systems. Private supplies were cleaned up and chlorinated.

Lime, chloride of lime, soap, spray cans, and crude oil were distributed and local crews were organized to clean up debris, bury or burn dead animals, and to open drainage channels, drain pools and spread oil to control mosquitoes. Medical supplies, including much quinine, were distributed liberally and where necessary; funds were furnished local chapters to provide for medical treatment for those unable to pay physicians. Hundreds of homes of malaria carriers were screened; five thousand pounds of yeast were distributed as part of the measures to prevent pellagra.

On June 5 a conference was held at New Orleans, at which there were present state health officers from the flood affected states; the Surgeon General, U. S. Public Health Service; Medical Director, American Red Cross; the Directors for the United States of the Health Division, Rockefeller Foundation; together with other representatives from these organizations.

The object of the conference was to receive reports of the state health officers in the flooded areas and to consider plans for the coöperation of the Rockefeller Foundation and the U. S. Public Health Service with the official health agencies in the flooded areas and the Red Cross in developing a permanent health program to meet the needs of the communities after the temporary program of health and sanitation of the Red Cross had been fully carried out.

The vast extent of the area involved, the large economic losses and other factors, such as the possibility of lowered resistance to disease due to poverty and hardship, and the development of pellagra made it apparent that a really effective sanitary rehabilitation and public health program was a long time job. The value of the full-time county *organization, or health unit, as it is generally called, had been strikingly* demonstrated during and after the flood and hence, plans were made to establish a health unit for a period of 18 months in 87 counties and parishes seriously affected by the flood.

The plans provide for a unit with the following personnel: health officer, public health nurse, sanitary inspector and clerk, with provision for travelling and incidental expenses. The budget is made up of funds from the county or parish, the state board of health, the U. S. Public Health Service, and the Rockefeller Foundation, the county's share nominally being set at 25 per cent but actually being determined by the community's ability to provide funds. Where investigation showed that the county was really unable to furnish 25 per cent of the budget, part or even all of this was contributed by the coöperating agencies.

The Rockefeller Foundation established a training school at Indianola, Miss., to train personnel to carry on the work of these units. On October 1, 45 units were in operation, 19 with full complement of personnel and 26 with from 1 to 3 people on the unit staff. In 17 more counties, plans had developed to a point where it was expected that the units would be in operation within a few weeks. This program not only seems the best and most practicable method of dealing with the post-flood problems, but since it is expected that many if not all of these units will be maintained after the 18-months period has expired, it will mark a real advance in the public health movement in the Mississippi Valley.

As this paper is presented to a gathering of engineers, the major part has been given to the sanitary features, but these were only a part of the task. Homes had to be repaired and rebuilt; deposits of silt removed from the towns; roads repaired; seed, tools, household equipment and clothes supplied; poultry and live stock replaced; and food

for man and beast furnished until the reclaimed lands brought forth new crops.

On September 3 the Red Cross was still feeding 62,486 persons, and 86,561 acres were still flooded. Owing to the second flood and other causes, probably 2,000,000 acres of crop land will make no substantial money returns this year. The Red Cross is still functioning in the area, which gives assurance that even though it may take some time to replace the huge losses, no one need suffer cold or hunger.

In conclusion, the writer ventures to depart from the subject of the paper to express the hope of the Valley that this great catastrophe will awaken the entire country to the realization that the Mississippi River System belongs to the country as a whole and not to the few southern states who have so frequently suffered through its floods, and that the nation, which built the Panama Canal and which counts its surplus funds by the hundreds of millions, will exert every effort to bring this mighty river under control; in brief, the hope and trust that the recent flood has been great enough to be the last one.

Purifying Mississippi Flood Water

Simple Equipment Used

EPIDEMIOLOGIST in the city of Baltimore, Md., V. L. Ellicott, M.D., found that many of the refugees would probably be without satisfactory drinking water on their return to their homes. He, therefore, experimented with the method used at the Montebellow Filtration plant in Baltimore, and found that the addition of one level teaspoonful of alum and one-half level teaspoonful of lime to a bucket of river water, dissolved, stirred for a few minutes and poured through a filter of muslin and absorbent cotton produced a perfectly clear water in a few minutes.

He gave demonstrations to the refugees in the camp and to groups of people living in flooded or partially flooded territory. Instructions, of course, were given for sterilizing the water with chloride of lime or by boiling after filtration.

Dental Hygiene Aspects of the School Health Problem*

HAROLD DEWITT CROSS, D. M. D., FELLOW A. P. H. A.

Forsyth Dental Infirmary, Boston, Mass.

WE ARE greatly indebted to Dr. Rogers † for giving us such a complete picture of the school hygiene activities of the country. While it does not appear to be a serious matter whether school hygiene is done by the school or health department, it is quite evident that one or the other should attend to it, with full coöperation and without interference by the other.

Suitable scientific medical inspection is undoubtedly of great advantage to the school child, and should be carried out as thoroughly as possible until we are able to have most of this work done in the pre-school age. Meanwhile, as Dr. Rogers points out, we must endeavor to keep our figures of "corrections" fairly close to those representing "defects." We must not overlook the responsibility, implied at least, to correct the defects discovered. The statement that "malnutrition is the source of practically all defects" in school children is undoubtedly true, although it is only within a very few years that this idea has been thought to apply to teeth.

Dentistry for children came about in a very logical way as the result of discovering the systemic effects in adults of diseased teeth. When an attempt was made to institute preventive measures for these conditions, it was found they did not yield to such treatment after the disease was established. In order to apply "prevention" it became necessary to get back of the diseased tooth—to reach it before the conditions developed which were responsible for the systemic symptoms. This made it necessary to go back to childhood, even to the age of 6 years or under, for very soon after that age cavities begin to develop.

If no cavities are allowed to develop, no large cavity encroaching on the pulp (nerve) of the tooth can occur, and if the pulp is not encroached upon, there cannot be a dead pulp (nerve), and without a dead pulp there cannot be a tooth "focus of infection," affecting other

* Read before the Child Hygiene Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

† See Present Status of School Hygiene, James Frederick Rogers, *A. J. P. H.*, Jan., 1928, p. 53.

parts of the body, such as joints, heart, kidney, etc. Therefore, from conditions found to exist by recent scientific investigation, taken together with the results of examinations brought to light by the draft reports of tooth conditions, children's dentistry is the only logical conclusion to be deduced for preventive work.

It took about five years to reach the conclusion that the only way to cure a focus of infection in the teeth was to avoid all the conditions leading up to it, that is, at least to avoid cavities of appreciable size; and several more years were required to bring to the attention of the majority of dentists the fact that the only way to avoid a cavity was to begin before the cavity developed—consequently with a young child.

Dentistry had its beginning as a mechanical trade. The advent of the dental school made it a profession, and the constantly expanding curriculum has gradually introduced the broader scientific attitude; but the profession is still largely dominated by the mechanical influence, and even now its work is still curative and reparative in character. Its growth and progress have been remarkable, but it has made no progress in controlling the occurrence of tooth diseases.

The idea of prevention is not so current even today as it should be, and there are many school dental clinics conducted along the old line of cure or repair for older children—which is not doing any particular good from a public health standpoint, but merely attempting to cure a very small number of defects which should have been economically and preventively treated 7 to 10 years previously. Clinics of this sort are usually advocated by dentists who are educated and trained to do only mechanical repair work, as only recently has the teaching of other measures been added to the dental school curriculum. These clinics in rare instances appear to keep almost up with the development of large cavities—so that after a 3- or 5-year period of work, the number of cavities in the younger children is practically the same as at the beginning, despite the fact that a very large number of fillings have been made for the older children. About the same results are obtained when a program of cleaning only, without any actual dentistry, is carried out. The number of children using a toothbrush, and the number of sets of teeth cleaned, sounds like a lot of progressive work, but no cavity is ever arrested in its development, or any defective enamel pit prevented from developing into a cavity by tooth brushing and cleaning, however beneficial it may be for the morale of the child, or assist in preventing some of the gingival (gum) diseases, such as pyorrhea.

The only dental clinic procedure actually giving results in terms of sound, healthy, lasting teeth, is that of early treatment, immediately after the eruption of the tooth, to care for developmental or organic de-

fects in the formation of the enamel by cutting out these defects and placing small fillings. This plan while not reaching to the point of preventing the defect, does accomplish in a very permanent manner the maintenance of sound teeth structure, not only for the time being, but into adult life, because these little "defects" are the cause of about 90 per cent of cavities and fillings later on—if they do not earlier cause the loss of the entire tooth.

This plan may not eventually prove to be the only or even the best method of conserving the dental organs, but so far it is the only one which has given any actual results in terms of good teeth. It is equally effective whether carried out in the Cleveland School Clinics; by the Association for the Improvement of the Conditions of the Poor, New York City; at Bonn, Germany; or at the Forsyth Dental Infirmary in Boston.

The statistics of Professor Kantorowich who has charge of the organization of school dental clinics, at Bonn, and about fifty other German cities are very enlightening. Kantorowich reports as follows:

Final results at the end of the 8th grade in public schools, 93 per cent with healthy permanent teeth; in (private) high schools at the end of the school term, 93.2 per cent with healthy permanent teeth.

At Forsyth, before the plan was fully worked out and adopted, it was possible to save three to four 1st permanent molars in over 90 per cent of the cases—82 per cent with four 1st permanent molars and 11 per cent with three, in a vital condition at the 8th and 9th grade age; and the extraction of similar teeth, in groups beginning early treatment, was reduced from 33 per cent to less than 0.5 per cent. (See following summary.)

RETROGRESSIVE CHECK-UP RECORD OF BOSTON PUBLIC SCHOOL EXAMINATION OF
6TH YEAR MOLARS—JUNE 1925

Forsyth Dental Infirmary For Children, Boston, Mass.

827	4	6-year molars present	=	82.7%
111	3	6-year molars present	=	11.1%
62	2 & 1	6-year molars present	=	6.2%
<hr/>				
1000	Cases			100.0%

Cases were begun as I-II-III grades.

Check-up was made on an average of 6 years after work was begun.

243 6-year molars were extracted before beginning record.

Teeth extracted after commencing work for group=Primary 8159 + 40 6-year molars and equals 1 6-year molar in every 200 teeth extracted; or $\frac{1}{2}\%$ were 6-year molars.

1914—1 6-year molar was extracted in every 3 teeth extracted.

(50% of 6-year molars were given root canal treatment.)

1925—1 6-year molar was extracted in every 200 teeth extracted in special groups which have been consistently brought for early care. (No 6-year molars were given root canal treatment.)

4 6-year molars were saved in 80% of cases.

3 6-year molars were saved in 11% of cases.

The results have been so satisfactory that the Dental Hygiene Council of Massachusetts recommended to the Division of Hygiene of the Massachusetts Department of Public Health, that this plan of early and immediate treatment be the only one to be officially advised to the various communities of the state in their efforts to carry on a program of dental hygiene. This plan provides for an educational and an operative policy. The American Association of Dental Schools has also taken up this work in connection with preschool children and is endeavoring to have coöperative clinical instruction given to both medical and dental students.

DENTAL POLICY—MASSACHUSETTS DEPARTMENT OF PUBLIC HEALTH

Division of Hygiene

Endorsed by: Dental Hygiene Council of Massachusetts.
Massachusetts Dental Society.

A widespread need has developed for a consistent and definite policy regarding dental hygiene. This need has been felt by both official and unofficial agencies, by dentists as well as by health officers. The policy outlined below represents the joint decision of the Massachusetts Department of Public Health and the Dental Hygiene Council of Massachusetts in this matter. By a vote of the Massachusetts Public Health Council it is the dental policy of the Massachusetts Department of Public Health.

1—*Educational Policy:*

The Department will supply communities with information concerning the following subjects:

- a. The advantage of beginning dental treatment and nutritional care early, especially of the primary teeth at 2-3 years of age, and the first permanent molar at 6 years of age
- b. The relationship of oral health to general health—benefits of a clean mouth
- c. The relation of nutrition to teeth development
- d. The importance of dental and nutritional care during pregnancy, infancy and early childhood
- e. The evidence of desirability of clinic work, and the desirability of employing a dental hygienist

(Facts will be furnished by Dental Hygiene Council.)

- f. Information as to the visiting and instructive dental hygiene clinic (Directed by the Dental Hygiene Council of Massachusetts)
- g. Cleaning of teeth to be done largely for the benefit of "contact" with the child to create interest in good health habits
- h. Stress the importance of periodic inspection (once a year)

2—*Operating Policy:*

- a. The staff should consist of dentists and hygienists. (Number depends on size of group served.) The dentist to do fillings and extractions. The dental hygienist to teach dental hygiene, clean, examine for fissures and cavities and follow up in the school. (Follow up in homes to be referred to the public health nurse.)
- b. Operating Policy defined:

The recommendations of the department as to policy of dental treatment are identical with that carried out at Forsyth Dental Infirmary for Children.

1. Concentrate on preschool children (age 2-3 years) and follow up through the grades, beginning on the lowest until the problem is under control for all grades.
2. Fill all fissures and pits immediately after eruption. Do no "root canal treatment" or conservative pulp treatment.
3. Extract all teeth not amenable to "simple fillings."
(Fill only such cavities as can be done without danger of pulp involvement.)
4. Do only emergency work for children over 7 years of age.

5. Keep records of all teeth extracted that have been previously filled—in order to check up on work of clinic.
 6. Discharge children at 13 years of age or after eruption of 2nd molars.
 7. Stress the importance of periodic inspection. (At least once a year—oftener if possible if the child is young.)
 8. Carry on clinic only so long as it is necessary to introduce and make more attractive and forceful the educational program, cleaning, fillings of fissures and pits, nutrition and dental care for prenatal period and early childhood.
 9. Extend clinic service to prenatal cases.
- 3—The Department offers to communities:
1. Consulting service of dental hygienist
 2. Dental educational material:
 - a. Printed Material
 - b. Posters
 - c. Slides
 - d. Exhibits
 - e. Moving Pictures
 3. Lecture service to selected groups
 4. Assistance in state well-child conferences, stressing nutritional side of dental hygiene and importance of early dental care
 5. List of dentists approved by Dental Hygiene Council
 6. Details and cost of dental clinic equipment that have been compiled by the Dental Hygiene Council

AMERICAN ASSOCIATION OF DENTAL SCHOOLS RESOLUTION

At the last meeting of the American Association of Dental Schools, the following resolution was passed and a committee appointed to carry it out:

WHEREAS, it is desirable that dental services for children of preschool age be generally provided, and that medical and dental students be brought into closer contact and cooperation when receiving instructions with regard to preventive medical and dental treatment of children from birth to school age, therefore be it

RESOLVED, that this association approves of the establishment of preschool age dental clinics in medical and dental schools, health centres and hospitals throughout the world and that a special committee be appointed immediately for the purpose of conducting and cooperating with other organizations in international propaganda for this object.

This same organization, restricting its activities entirely to the dental hygiene phase of dentistry, and made up of representatives of all of the dental societies of the state, has adopted resolutions, the chief features of which are as follows:

WHEREAS, up to the present the attention of dentistry has been centered mainly on the work of restoring lost dental tissue, the only hope of real progress lies, in the prevention or early control of dental diseases. . . .

Prevention, to be effective, must be applied early in the life of the individual—and early in the life of the tooth. . . . That dental service must begin early and be systematic and periodic in order to obtain the maximum of prevention with the minimum of operative work, and to properly educate the child in habits of oral hygiene. . . . That in the aim to attain prevention of systemic and dental disease—(a) No defect is too slight to receive definite attention. (b) The temporary teeth should receive as much care as the permanent ones, in order to promote the proper development of the jaws and head, and to maintain function. (c) Particular care and attention should be given to developmental pits and fissures, whether occurring in primary or secondary teeth, or whether decay is or is not present. That the Dental Hygiene Council of Massachusetts

declares for the principles and practice of children's dentistry, and maintains that the most effective dentistry that can be done for any individual is the service rendered between the 2nd and 14th years of age.

These principles, in turn, have been adopted by fifteen state societies—the Canadian Dental Society, The VII International Congress, the International Dental Federation and the American Dental Association.

MORE PREVENTIVE EDUCATION NEEDED

In spite of all this interest and publicity, more is needed, for there are still many dentists, just as there are physicians, who do not as yet take much interest in either prevention or such early care, that no treatment of actual disease is involved.

The public, perhaps, is a little in advance of these dentists in their belief in the theory and application of prevention, but they are really further behind than they should be, in what they should know and expect from preventive dentistry or dental hygiene, and much effort will be needed to make this information of practical value.

In the Forsyth Infirmary, all clinical factors of a preventive nature dealing with tooth diseases are carried out to as great an extent as the present status of knowledge permits. Older practices have been given up and new ones adopted as rapidly as some procedure has been found to contain a larger proportion of features of prevention. Prevention is here used in the sense of a real avoidance of a condition or occurrence as it is in medicine, and not the usual dental meaning of merely an improvement in an already established technic or procedure.

The usual and more complicated dental technic is discarded for a very simple type which is all that is needed in caring for the early and simple tooth defects. The lack of complicated technic and the care of extensively and badly broken down cases has frequently been remarked upon, to the exclusion of noticing the continued maintenance of good tooth and systemic conditions, and the avoidance of defects.

In order to accomplish results which are at all preventive in character, it is not only necessary to carry out certain simple technical procedures, but the case must be in a suitable condition to make these procedures possible. This involves chiefly the opportunity to treat the cases *before* conditions have developed beyond a very early stage, and consequently the age of the child is of as much importance as are the clinical procedures. In other words, it is necessary to have both the technic and the time of applying it correlated, in order to obtain the definite advantages which are possible.

The greatest difficulty has been, and is still in getting parents, nurses, physicians, and dentists to appreciate the importance of early attention, so that in any community the age question is more of a problem

than that of clinical procedures, which have been well standardized and put to a successful test.

Large numbers of children, 2 to 3 years of age, are treated to preserve their primary teeth by early treatment of pits and fissures, as it is the aim to fill all cavities within 6 weeks after eruption, whether in primary or secondary teeth. It is not yet possible to do this for the primary teeth to the same extent as is now done for the secondary, on account of the difficulty of getting in touch with children of this age. However, through the baby hygiene and preschool age children's associations, a definite gain is being made each year, although more time probably will be required to place the treatment of primary teeth on a par, in numbers, with that of 6-year molars.

The foregoing plan, while extremely simple and non-technical in character, is giving "end-results" at 16 years of age, in healthy teeth which have had the minimum of dentistry, as early repair work, and the four 1st permanent molars with vital pulps and small fillings are retained. This is a result which technical (orthodox) dentistry has never produced and never can, because it does not aim to prevent, but only to cure and repair.

School dental hygiene is greatly hampered by the lack of preschool work, and many dental defects developing between the ages of 3 and 6 years leave an impression on the child which no amount of school age treatment can undo. It is true that the first permanent or 6-year molar cannot be treated until school age for many children, because it has not erupted, and consequently much of this work must be delayed until school age. However, the primary teeth, in the majority of preschool children are very seriously broken down, and are in as bad a condition as is found in the permanent teeth when uncared for at 10 to 12 years of age.

Inasmuch as under the subject of school hygiene must be considered all of the defects existing at the time of entrance to school life, it appears very logical to include certain preschool hygiene activities which will lead to a reduction of school age defects. This perhaps is not true to any greater extent in dental than in other phases of health defects, but the possibilities of correction in this direction are so great, and the effects both locally and systematically so definite, that such activities cannot be much longer overlooked or neglected.

It has been shown that a large proportion of cervical adenitis and enlarged tonsils are very frequently caused by broken down and abscessed primary teeth, and undoubtedly the first infections, leading later to endocarditis, joint and kidney affections, is often attributable to these serious primary tooth conditions.

Why then, if school hygiene has for its object "to maintain the highest practicable level of health in school pupils," is it not reasonable that school hygiene activity be directed towards the feature (i. e. pre-school correction and prevention) which will simplify the correction of school-age defects—whether this be as actual repair work, or along educational lines.

First grade children require approximately ten times as much work to be done on their neglected primary teeth as upon the newly erupted first permanent molars (6th year). This takes school time and school expense to correct from 6 to 15 large cavities in primary teeth, which might have been done in one-tenth the time and expense a year or two previously. Teachers and nurses complain about this loss of time, yet very few make any effort to have this work done earlier. The difficulty of preschool children not being congregated to facilitate group work, is a complication, but one which could easily be overcome, and at a much lower cost than doing the enormous amount of corrective work after they are in school.

There may be some difference of opinion as to whether prenatal work should logically be included in school hygiene, but some time we may act with sufficient coördination in our health activities to have things done where and when it is necessary to produce results, regardless of who or of what department does it.

Most of the defects (at least 85%) of the primary teeth are produced during the prenatal period and as these teeth are fully formed at birth it is evident that the poor teeth of a child of 5 years, is the direct result of poor prenatal conditions. In turn the poor tooth conditions appearing in the child's secondary set is attributable, to a large degree, either directly or indirectly to the poor primary tooth conditions.

Education in dental hygiene, as in all other phases of the school hygiene problem, is undoubtedly more fundamental and more important than the purely corrective features. The results, to be sure, are always slower than a spectacular correction of defects, but will in time lead to a definite decrease in the necessity for the now excessive corrective procedures.

When parents, teachers, nurses, physicians, and dentists know the possibilities which may be achieved by beginning early and following along each step, beginning with the health of the young people before parenthood, and consequently antedating the prenatal, infant and childhood stages, we shall not need to talk so much about correcting defects, not only dental but all others, as a school hygiene proposition.

Up to within 5 to 8 years, the teeth have been treated in a purely mechanical way and almost as though they were a foreign substance

rather than an actual organ of the body. Also their destruction by decay has been believed to be a local process entirely, rather than dependent upon their vital resistance brought about by the state of nutrition existing in the body as a whole. The ideas now generally accepted by the most advanced among the medical and dental professions really place all of the factors, except their actual repair as a medical problem, and on the same basis as defects and deficiencies of other organs to function properly.

The teeth are, however, peculiar in their response to changes in nutrition, the dental tissue being, so far as is known, the first to respond to a disturbance such as a slight deficiency in certain substances. A few days on a deficient diet shows its result in the structure of developing teeth of pigs and monkeys, and this has also been shown to apply to children whose diet has been very carefully supervised and checked by a control group.

GOOD TEETH RESULT FROM ADEQUATE NUTRITION

It is now an established fact that if adequate nutrition can be maintained during the tooth formative period that good teeth without serious defects will result; also that to maintain these teeth in good health there must be a continuance of good nutrition.

Most of the cavities of children's teeth arise, not in an originally perfect tooth, but in defects of development caused by poor nutrition before eruption. These defects of course develop into cavities through the well known processes of fermentation, fostered by secretions from abnormally functioning glands, upset by the lack of certain food essentials, in addition to the fact that the tooth itself does not receive the necessary nutrient material for the blood stream.

With the present knowledge in regard to the causes and control of dental defects, let us hope that the time is near when the people as a whole shall reap the advantages of this knowledge, and a real modern dentistry will come into general application, so that with our highly civilized development and knowledge our children may grow to adult life with sound and lasting teeth, a set "permanent" not only in name, but in reality.

American Social Hygiene Association Report

A BRIEF summary of the achievements of the American Social Hygiene Association for 1927 has been prepared in mimeographed form for distribution. In 5 pages the research work, aid given to municipalities in their civic house cleaning projects, coöperation with national health groups in stimulating scientific work in relation to the social diseases, the educational program and other activities of the A. S. H. A. are interestingly told.

Chemistry and Health*

HARRY W. REDFIELD, PH. D., FELLOW A. P. H. A.

Mendham, N. J.

A PROPER consideration of the subject of the relation of chemistry to health necessitates first that we fix in our minds a number of fundamental facts:

1. Human bodies are the most marvelously intricate and finely balanced examples of masses of chemical substances, actuated and controlled by exactly coördinated chemical reactions, which have ever existed or which ever will exist.

2. Life is the highest and most complex expression of the transformation of matter and of the transformation of energy. Chemistry and physics are the fundamental sciences of the transformation of matter and of energy and are therefore the sciences which must ultimately explain and regulate life.

3. The speed with which the complicated and coördinated chemical and physical changes constituting life take place, is of vital importance. Life, in fact, is dependent on the proper fine adjustment of the time relations of a great many interdependent actions in the body; the rate of the heart beat, the rate of respiration, the rate of metabolism, the rate of digestion, the rate of elimination—all matters of physical chemistry.

4. Furthermore, life is dependent upon the maintainence of stability in the colloidal systems which constitute our organs and tissues, the cells of which these are made and the fluids which bathe them—matters of colloidal chemistry.

In short, every breath we take, every movement we make, is the result of chemical changes within the wonderfully organized communities of cells which constitute our bodies. These chemical reactions are so complicated that we understand them but hazily. They, in turn, induce further chemical reactions which we also do not understand. But this much we do know. It is only when these multitudinous chemical changes, which are going on all the time, some with inconceivable rapidity, some more slowly, are proceeding in an orderly fashion that we are in a state of health. When they are abnormal in character or not properly coördinated, they are a direct cause of disease, as in gout, diabetes, goiter, and autointoxication. When abnormal, they may also be the indirect cause of disease through lowering the natural resistance of the body to invading disease germs, which in turn do their damage through the chemical substances which they produce—the toxins.

How much has chemistry done to determine exactly what are the normal constitutions and reactions of the organs, tissues, cells and fluids

* Address of the Chairman, delivered before the Food and Drugs Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

in the body? In comparison with what remains to be done, it has accomplished very little.

Chemistry has devoted its chief efforts to bringing back to normal, as far as possible, the course of the life processes after they have been disturbed and upset by some agency. Indeed, the very name—chemistry—refers to the land of Chêmi (Egypt) where the science originated in the temples in which priests experimented with simple chemicals for the preparation of medicinals.

For many centuries the connection between medicine and chemistry was so close that in the 16th century the great physician and chemist, Paracelsus, stated: "the true purpose of chemistry is not to make gold, but to produce medicines." It was Paracelsus, you will remember, who introduced into medicine the use of mercury, lead, sulfur, iron, arsenic, copper sulfate and laudanum. Chemists since that time have devised many medicinals to bring abnormally reacting human bodies back to a state of comparative good health. Their contributions to curative medicine have been far larger than have been their contributions to preventive medicine.

To curative medicine the chemist has brought natural therapeutic agents too numerous to mention. He has gone further and improved on nature in many instances by extracting from natural, impure medicinals the pure principles, such as the alkaloids; he has fabricated previously nonexistent medicinals of great value, such as procaine, arsphenamine and many of the sedatives; he has even prepared the pure principles of some of our organs of secretion, such as epinephrine and thyroxin; he has made much progress toward isolating those vitally important principles of our food, the vitamins, to whose lack is due the deficiency diseases.

Truly the investigators in the fields of chemotherapy and nutrition have done much to aid mankind and to further health. As evidence, however, that this work is nowhere nearly finished, I quote Dr. Charles Herty to the effect that the biggest research task confronting chemistry today lies in the field of human health. What are some of these unsolved problems to which he refers?

LINE OF EFFORT STILL TO BE ATTEMPTED

There is a great opportunity to prepare specific medicants for the scourges of tuberculosis, cancer, endocarditis and a host of other diseases. The number of specifics which we have is pitifully small. There are many vital secretions the isolation of whose pure principles could be undertaken with great profit to health.

Another intensive line of effort should be the attempt to isolate the

pure principles of antitoxins, bacterial vaccines and serums, now so much depended upon as to be styled the Big Berthas of curative medicine. The fluids which are now used, valuable as they are, contain, no doubt, only very small quantities of the pure active principles, mixed with large proportions of inert or even harmful matter, and their use is attended with the serious dangers of anaphylactic shock and other complications. That such purification would result in far better therapy is obvious. The isolation of such specifics should be followed by the exhaustive study of structure, revealing the why and wherefore of action, opening up the way to refinement and improvement. This problem is perhaps the very greatest immediate investigation awaiting the attack of chemo-medical research.

Very little has been done toward solving the fundamental problems of physical and colloidal chemistry to which reference was made earlier; the profound study of our time reactions and their regulators; the study of colloids as the basis of investigation of our organs of secretion. Practically this whole field is open and it is a large and important one.

But the very heart of the problem of life, the highest form of chemical change, lies in the deep and complete study of the chemistry of the body cells. This is the most important and also by far the most difficult problem of all. Its solution is vitally necessary for that complete mastery of science over life, which will give man the wisdom to maintain health and to increase the span of life. Herein lies the greatest opportunity of the chemists of the future. Already the trend is in this direction and the work of curing or preventing disease is tending toward a study of the means by which conditions for normal cell processes may be maintained or restored after any disturbance. The importance of increasing our knowledge of the mechanism of the chemical processes operating in the cells of our bodies wherein all the fundamental reactions of life originate and take place, cannot be overemphasized.

While many definite chemical substances have been isolated from human tissues, the identification of which is a distinct contribution to our knowledge of the body cells, no comprehensive and exhaustive study of the contents of even a single type of cell has ever been attempted. Our knowledge of cells from a strictly chemical point of view is scanty indeed. To those who finally elucidate the problems of chemistry and physics in the ultimate field of cell life will fall the honor and gratification of making the greatest contribution of all in maintaining health, preventing disease, and so lessening the need of curing disease.

I have tried to convey to you what I consider is the gravest responsibility and the greatest opportunity of the Food and Drugs Section in the furtherance of the public health. While I do not decry food and

drug control operations, and while I do not seek to minimize the benefits which health in general has received from such operations, I call your attention to the fact that there are other associations than the A. P. H. A. designed primarily to cover the interests of food, drug and dairy control officials. Furthermore, while I shrink from attempting to formulate a policy for future chairmen of this section, I would like to place before them for consideration the proposition that this section can do its utmost for public health by stimulating such research as I have briefly outlined and by securing for its Annual Meeting programs, as far as possible, the presentation of original research along these lines.

NOTE: To those who would pursue this subject more exhaustively, I commend the little book *The Future Independence and Progress of American Medicine in the Age of Chemistry*, published by the Chemical Foundation Inc. from which I drew quite freely and at times almost verbatim in preparing my remarks.

Zoning Progress In the United States

EDWARD M. BASSETT of the Advisory Committee on City Planning and Zoning of the U. S. Department of Commerce and counsel for the Zoning Committee of New York, discusses under the title of "Zoning in the Courts" recent court cases related to zoning.

In brief, Mr. Bassett points out that the constitutionality of zoning ordinances depends upon the question of whether they are reasonable, impartial and based upon the health, safety, morals and general welfare. When these requirements are complied with and the state in which the laws are enacted have Enabling Acts specifically granting to communities the power to zone, when the zone systems are worked out on a basis of careful study of the community's need and development trends and when a board of appeals or adjustment is established with power to vary the strict letter of the ordinance, the chances of such ordinances being declared constitutional are excellent.

In the report on "Zoning Laws and Ordinances" by the Division of Building and Housing of the Department of Commerce, a list is given of the communities which now have zoning ordinances. More than 30 million people comprising in excess of 55 per cent of the urban population of the United States are protected by zoning.—Edward M. Bassett and by the Division of Building and Housing of the United States Department of Commerce.

The Problem of Decolorization

ESTHER WAGNER STEARN AND ALLEN E. STEARN, PH.D.

University of Missouri, Columbia, Mo.

PROBABLY the greatest lack of uniformity in staining results are met with in such technic as the Gram differential method. While certain organisms can be made to exhibit such a vigorous affinity for basic dye as to be classified always as Gram positive, and certain other organisms exhibit such a weak affinity for the same dye as to be classified always as Gram negative, there is also a large number of "border-line" organisms, the Gram classification of which is somewhat equivocal. It is in the classification of the last type of organism that the characteristics of the decolorizer play an important practical rôle.

For example, the substitution, for the chloroform of Claudius' modification of the Gram technic, of aniline, ethyl alcohol, acetone-alcohol, etc., leads to unreliable results.¹ All of these substances decolorize, but they do not all give corresponding differentiation. Grimme² finds that carbolic acid decolorizes carbol fuchsin stained spores (Kugeln) of *Pseudomonas* species better than alcohol.

In the authors' experience in staining procedure, three factors seem of importance in the choice of a decolorizer. In certain technics one factor is of more importance, and in other technics another.

1. *Solubility of dye in decolorizer*—This factor is generally recognized and is merely enumerated for completeness.

2. *Effect of decolorizing liquid on the pH of the stained tissue*—A basic dye is retained to a much smaller degree in acid than in neutral or alkaline solution.³

3. *The acidic or basic character of the decolorizer, aside from its electrolytic strength*—The alcohols, though ionized to such a small extent as to have practically no effect on the pH of the tissue which they bathe, are nevertheless distinctly acidic in character. This is shown, for instance, by the ease with which certain metals such as sodium or potassium will displace their hydroxyl hydrogen, forming the corresponding alcoholates.

To determine the effect of this character on the decolorizing power of liquids, experiments were made on organisms stained with both acid and basic dyes. The results are summarized in Table I.

Fixed smears of *B. coli*, stained either with gentian violet or acid fuchsin, were found to be easily decolorized by acetone in the absence of any mordant. If the gentian violet stained smear was mordanted with weak sodium carbonate solution, the dye was strongly retained, as shown by the failure of acetone to decolorize, while mordanting with

weak acetic acid solution caused retention of acid fuchsin. *B. cereus* behaved in the same manner except that acetone failed to remove the gentian violet even when no mordant was employed. For each decolorizer studied, therefore, two slides of an organism, either *B. coli* or *B. cereus*, or two slides of each in some cases, were prepared. The one slide was stained with gentian violet and mordanted with weak sodium carbonate solution, the other was stained with acid fuchsin and mordanted with weak acetic acid solution. Neither water nor acetone would decolorize any of the smears thus treated.

The decolorizers which are normally liquids were used directly in the commercially obtainable form. For example, the formaldehyde was the 40 per cent solution, the ethyl alcohol was the 95 per cent liquid, etc. In the cases of the easily soluble solids such as urea, acetamide, etc. (marked (S) in the table), a 10 to 15 per cent aqueous solution was employed, while in the cases of the difficultly soluble solids (marked (S') in the table) an aqueous solution saturated at 50°C. was employed. It was determined that pure water at this higher temperature did not decolorize the smears which were being thus treated.

The general behavior of the various decolorizers seems to be brought out fairly well in the table. Acidic substances apparently tend to decolorize gentian violet stained organisms without affecting the fuchsin stained ones appreciably, while the reverse is true for the basic substances. Although the results may be partly explained on the basis of the established pH effect on the stability of the dye-protein compound which is probably formed during the staining, it seems highly improbable, especially in the cases of the non-aqueous unbuffered liquids, which, however, show the same behavior as the aqueous solutions, that the selective decolorization is entirely due to a shift in pH. Also, while the relative solubilities of the dyes are different in the different liquids, this fact cannot account for their behavior. In many of the liquids the two dyes studied seem almost equally soluble, and in some cases, notably that of the solution of phthalimide, it was noted that the acid fuchsin was dissolved from the slide much more easily and much more completely than was the gentian violet. In fact it was almost impossible to remove the dye completely from the slide itself. Nevertheless the gentian violet stained organisms were decolorized, whereas those stained with the acid fuchsin retained the stain.

The authors have explained these results to themselves, in accordance with the postulated equilibria obtaining in such systems,⁵ as partly due to mass action effects. Thus in the one case the acidic substances are competing with the acidic bacterial protein, i.e., protein brought to the alkaline side of its isoelectric point by treatment with sodium

TABLE I

DECOLORIZER	IONIZATION CONST. (Approx)	DECOLORIZING EFFECT ON			
		B. COLI G. V.	FUCHSIN	B. CEREUS G. V.	FUCHSIN
<i>ACIDIC</i>					
Phenol	10^{-10}	+	—	+	—
m-cresol	2×10^{-8}	+	—	+	—
Phthalimide (S')	5×10^{-9}	+	—
Methyl alcohol	+	— +	— +	— +
Ethyl alcohol	+	—
N.propyl alcohol	+	—
N.butyl alcohol	+	—
N.octyl alcohol	—	—	—	—
Benzyl alcohol	+	—
Formaldehyde	2×10^{-11}	+	—	+	—
Acetaldehyde	5×10^{-13}	+	—
Paraldehyde	+	—	+	—
Acetoacetic acid	2×10^{-9}	+	—
(ethyl ester)					
<i>BASIC</i>					
Urea (S)	10^{-14}	—	+	—	+
Pyridine	10^{-9}	—	+	—	+
Aniline	4×10^{-10}	—	+	—	+
Quinoline	10^{-9}	—	+
Benzamide (S')	—	+
p-nitroaniline (S')	10^{-13}	—	+
L'Naphthylamine (S')	3×10^{-19}	—	+
Caffeine (S')	$< 10^{-10}$	— +	— +
Acetamide (S)	3×10^{-15}	— +	+
Dimethylaniline	2×10^{-10}	—	— +
(crude)					
<i>AMPHOTERIC OR MIXED</i>					
Glycine (S)		— +	+	—	— +
Alpha-alanine (S)		—	+	—	— +
Urea-formalin		+	+	+	+
Urea-acetone-water		+	+
<i>NON-POLAR. (?)</i>					
Acetophenone		— +	—
Carbon tetrachloride		—	— +
Ether		—	—
ACETONE		—	—	—	—

The ionization constants are taken from Scudder. * (S) denotes a 10 to 15% aqueous solution; (S') denotes an aqueous solution saturated at 50°C. (—) denotes no appreciable decolorization; (— +) denotes only slight decolorizing effect; (+ —) denotes slight retention of dye while (+) denotes complete decolorization.

carbonate solution, for the basic dye, gentian violet. The preponderant mass effect of the decolorizer over the protein results in comparatively easy decolorization, since the ionization constants of the protein are probably small and of an order of magnitude not significantly greater than those of the decolorizers. In the case of the fuchsin stained tissue we have basic protein, brought to the acid side of its isoelectric point by the acetic acid treatment, retaining the acid dye. Under such conditions there would be no chemical mass effect of the decolorizer, and decolorization would have to depend on the solubility distribution of uncombined dye. Naturally the removal of all uncombined dye by decolorizer would be expected to lead to a certain amount of dissociation of the dye-protein complex, and under any circumstances long continued treatment with any decolorizer will effect removal of stain. Differential decolorization is entirely a matter of relative velocities, and thus in the above work the slides were decolorized until the decolorizer appeared free from stain.

With basic decolorizing agents the reverse conditions hold, and we find the fuchsin stained organisms easily and completely decolorized while the gentian violet is retained.

Even with different acidic substances there is a distinct difference in the speed of decolorization. This has been rather strikingly shown by Kisskalt⁴ in a series of tests on 39 organisms. The decolorizing power of the lower alcohols was studied, and he found that, with the exception of the vibrios and the fluorescent bacteria, practically all bacteria retain gentian violet if amyl alcohol is used as decolorizer. Butyl alcohol decolorizes more strains than amyl, propyl more than butyl, ethyl more than propyl, while methyl shows the widest decolorizing power.

The results in Table I bring out to a certain degree the same fact. When the jump is made from butyl to octyl alcohol all decolorizing effect seems to have been lost. This order is exactly what would have been predicted on the basis of the above explanation, both from the relative molecular concentrations, which decrease with increasing molecular weight, and also from the probable order of acidic strength, which one would expect to decrease with increasing molecular weight,⁵ the heavier hydrocarbon groups having more and more masking effect on the polar properties of the hydroxyl group.

Strictly speaking, caffeine should be classed as amphoteric, but its basic ionization constant is so much larger than its acid ionization constant,⁴ as compared to glycine and alanine, that it is placed with the basic substances. The differential effect is in the same direction as that of the other bases but is by no means so marked.

Glycine and alanine are amphoteric and highly buffered, and it is possible that their effect is largely due to bringing the smears to their isoelectric points, both of which are at a pH of about 6. Either basic or acidic ion is then available for any mass effect. Such a pH is within the isoelectric range of *B. Coli*,⁷ though from the pH effect on the retaining power respectively of gentian violet and acid fuchsin as shown by the authors,⁷ the slightly more rapid decolorization of the fuchsin stained smear, as observed, was to be expected. In the case of *B. cereus*, gentian violet is more strongly retained at a pH of 6, which is on the alkaline side of its isoelectric range.

The urea-formalin mixture behaved as expected. When urea is mixed with acetone and a little water is added one would not necessarily predict, from the general behavior, as shown in the table, that the gentian violet stained smear would be decolorized. It is possible that the presence of the urea and water cause a shift to a higher concentration of the enolic acidic form of acetone and that the effect is so produced.

The authors have found that, unless there should be some special reason for the choice, for instance, of a basic decolorizer, as for example for the purpose of obtaining sharp differentiation between a strongly Gram positive and a weakly Gram negative organism, acetone furnishes the most nearly generally applicable decolorizer. While the enolic form of acetone is no doubt acidic in character, as evidenced by the liberation of hydrogen upon treatment with sodium, this form does not seem to be present in the ordinary pure liquid to an appreciable extent, and we have probably a substance which is neither sensibly acidic nor basic. Thus two of the above three factors tend to be eliminated by its use. It is also a decolorizer in which most dyes are sufficiently soluble for effective removal. Such is not the case with either ether or carbon tetrachloride, in which liquids both gentian violet and acid fuchsin are only extremely slowly soluble if they are dissolved at all.

In differential staining methods it is obvious that the dominant factor in the results (and ideally the only factor) should be differential retaining power of the organism for the stain, or if we accept the chemical point of view, the stability of the dye-protein compound. It must be borne in mind that all of the smears prepared for decolorization in this work were prepared under such conditions that the dye-protein compound was, from the point of view of differential staining methods, stable.⁷ The ideal decolorizer, then, should show this to be the case, but should likewise effectively decolorize smears where such compounds are not stable. Among the common decolorizers acetone seems to come nearer fulfilling these requisites than any other substance tried.

In agreement with the general experience of the authors, Stitt⁸ makes the statement that, as a decolorizer, "acetone is preferred by many due to the fact that it is more rapid in its decolorizing action on Gram negative organisms, yet slower to decolorize positive organisms."

Health Group to Meet

THE Third New York Health Conference will be held at Hotel Roosevelt, New York, N. Y., February 23-24. The meeting is being arranged under the following official and voluntary agencies:

U. S. Public Health Service
 New York State Department of Health
 New York City Department of Health
 New York State Medical Society
 Milbank Memorial Fund
 Bellevue-Yorkville Community Health Council
 State Charities Aid Association

At this time the State Committee on Tuberculosis and Public Health of the State Charities Aid Association will hold its semi-annual meeting.

The Advisory Council of the Milbank Memorial Fund will also meet to review the work being accomplished in the health demonstrations in Cattaraugus County, Syracuse and the Bellevue-Yorkville district in New York City.

Committee on Administrative Practice*

THE COMMITTEE on Administrative Practice was reorganized and placed on a permanent basis at the Buffalo meeting of a year ago. It is now composed of 12 members appointed by the President of the American Public Health Association to serve for 4-year terms, in overlapping groups, so that 3 members are appointed each year; plus the Executive Secretary of the Association and the 3 officers of the Health Officers section as *ex officio* members, 16 members in all.

The committee, as its work has developed during the past 5 years (with its Field Staff), has come to constitute essentially the technical service division of the A. P. H. A. organization. It appears to have at the moment 3 essential and primary functions. These are:

A. The collection of material in regard to existing health department practice by surveys and questionnaires

B. The critical analysis of the data thus obtained and the formulation of the results of such analysis in the shape of model forms and programs

C. The making available, to individual communities, of the results of procedures A and B by operating an information service and by making on request more or less detailed local surveys and appraisals

A fourth function, that of organized publicity to further the improvement of health department practice by the wider use of the technical machinery now available, has been more or less forced upon the committee; but much of this work will now be shifted to the recently organized Promotion Division of the A. P. H. A. office.

We may conveniently review the work of the past year and the plans for next year under the headings just outlined, although the first two functions, the collection of data and the development from them of model forms and programs, must necessarily be considered together since they are intimately interlocked.

The most important single task, upon which the committee is now engaged is the revision of the *Appraisal Form for City Health Work* under a sub-committee of which G. T. Palmer, Dr. P. H., is chairman. This *Appraisal Form*, which was placed in your hands in January 1926, has exhibited a usefulness beyond our highest expectations. It has been said, and, we believe, with some justice, that no single factor has ever done more than has the use of this *Appraisal Form* to develop city health department practice in the United States; and it has been used to some extent even in foreign countries.

* Report of the Committee, presented to the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

However, the committee has felt from the beginning that there were two very real dangers in the practical application of the appraisal principle. It might, on the one hand, invite unjustified and damaging criticism of departments having low scores; and it might, on the other, lead to undue standardization and to stagnation on the part of cities having high scores. The first of these hazards has, so far as we are aware, been completely avoided by the use of the *Appraisal Form* in an individual city only with the approval and on the request of the health officer and by the avoidance of any comparison of total scores obtained by various cities on a comparative basis. The second hazard, we have planned to obviate by revision of the *Appraisal Form* at 3-year intervals, and the first revision will be completed during the coming year and presented at the 1928 Annual Meeting. It is planned, not only to alter items in the present form which have been shown to be theoretically and practically unsound, and to increase levels of attainment required for a perfect score to keep pace with current progress; but also, if possible to include certain new items not now included at all. Individuals and organizations interested in mental hygiene and in industrial hygiene, and in the control of heart disease, cancer and malaria, will be asked to submit for their respective fields model administrative programs with appropriate numerical ratings of various activities on an objective basis; and if it proves that such programs and ratings can be prepared they will be included in the 1929 revision.

RURAL COMMUNITIES

A second project, of major importance, is the attempt to extend the appraisal principle to cover the health machinery of rural counties. The sub-committee on this project, under E. L. Bishop, M. D., has prepared during the year a tentative *Appraisal Form for Rural Health Work*. This form was published some time ago and has already been extensively tested out in practice by the committee in Tennessee and to some extent in the states of New York, and Georgia. County or district health officers from 15 states have written to us for 402 copies of these forms, and up to October 1, 1927, 652 copies in all had been distributed. This tentative form will be continued in experimental use till 1929.

In order to proceed soundly with the preparation of programs for rural health work, it seems to us essential that we should have the same broad basis of knowledge which was obtained for city health services in the comprehensive surveys of 1920 and 1923. Dr. Bishop has therefore prepared a definite program for a 2-year study in which 50 typical counties should be surveyed, covering all sections of the country and all

degrees of public health development. He presented this program at the Surgeon-General's Annual Conference of State and Territorial Health Officers last spring. The matter was referred to a committee of the conference on Standard Forms for Reporting County Health Work, S. W. Welch, M. D., chairman. Dr. Bishop's committee and Dr. Welch's committee are now working on the problem with every prospect of hearty agreement. It will be necessary, however, to obtain special funds to the extent of \$25,000 if this work is to be undertaken.

UNIFORMITY OF PRACTICE

In addition to the *Appraisal Forms* which cover in a general way the whole balanced program of community health service, your committee has proceeded actively during the year with the study of certain details of health department procedure which seemed to lend themselves to analysis in the direction of uniformity of practice. Thus, a Sub-committee on Record Forms, with G. C. Ruhland, M. D., as chairman, has rendered a notable service during the year in the preparation, after a vast amount of correspondence and critical study, of sets of model forms to be used in connection with the communicable disease service, the laboratory service, the school medical inspection, and the nursing service of the health department. These 4 sets of forms constitute the second definite evidence of work completed by the committee during 1927. Dr. Ruhland's sub-committee is now proceeding with the preparation of similar forms for use in connection with tuberculosis and venereal disease.

The Sub-committee on Model Health Department Reports, C. Hampson Jones, M. D., chairman, has prepared a preliminary analysis of the functions and contents of a model annual report, a third concrete result of our sub-committee activities presented at this convention. Topical outlines for the various sections of the annual report will be worked out in detail during the coming year.

The Sub-committee on Model Ordinances, H. F. Vaughan, D. P. H., chairman, is at work on a schedule of the main essentials which should be the objectives of a health code, and its final report is promised by the spring of 1928.

An important special problem, that of the relation between the health department and the local hospitals has been considered by a sub-committee, of which Michael M. Davis, Ph. D., is chairman, and his very interesting report giving the results of a questionnaire sent out to 247 health departments and to 1365 hospitals and dispensaries, and supplemented by field visits by our staff, presented at this meeting, will be published later.

The problem of the hospital and the clinic has been forced upon the attention of your committee, not only as coöperating agencies in the primary activities of the health department but, as themselves, in their very essence a part of the machinery for community health programs. We have been called on during the year to make special surveys of the hospital situation in St. Louis and Scranton and have undertaken a study of the dispensary situation in Cincinnati. In order to meet future demands of this kind the scope of Dr. Davis's sub-committee has been enlarged and its title changed to Sub-committee on the Organized Care of the Sick. It has been asked to prepare a suitable survey schedule for the study of hospital and dispensary service and to supervise the field service of the committee in this important field. The work projected will continue to be carried on, as it has been during the past year, in close coöperation with the officers of the American Hospital Association and the function of the sub-committee is limited to the study of hospital and dispensary service in regard to community needs and relationships and will not include details of the construction or operation of such institutions.

Mention should be made of one other sub-committee, that on Analysis of Public Health Procedures, Prof. A. W. Freeman, chairman, which has not been active during the past year but from which we hope much in the future. It is the function of this sub-committee to attempt, step by step, the analysis of the demonstrated values of various community health activities in terms of actual life saving—a problem of enormous difficulty but the solution of which will alone give us the ultimately sound basis for the standards and the appraisals now necessarily grounded in the main on group judgment and empirical experience.

A special sub-committee, with Haven Emerson, M. D., as chairman, was appointed as a result of action taken by the American Public Health Association at Buffalo to present to the American Medical Association the invitation to create a joint standing committee of conference between the two organizations on the inter-relationships between the public health movement and the medical profession. Conferences on the plan have not yet proceeded far enough to require any further official action. Your committee desires, however, to express its feeling that if the American Public Health Association does take part in any such permanent conference committee it should do so through a special committee named by the President of the Association for the purpose and not through the Committee on Administrative Practice.

We may now proceed to a consideration of the third primary function of the committee, the translation of its general program into concrete action through local surveys and appraisals. It is this work which

of course occupies the major share of the time of our very able staff, including Dr. Walker, Dr. Drake and Miss Phillips. During the past year we have made more or less complete surveys and appraisals in Athens and in Clarke County, Ga., Burbank, Calif., Cattaraugus County, N. Y., Chicago, Ill., Cincinnati, O., Fargo, N. Dak., Glendale, Calif., Hingham, Mass., Lowell, Mass., Quincy, Mass., Rutherford County, Tenn., Salem, Ore., Scranton, Pa., St. Louis, Mo., and Syracuse, N. Y., while more or less definite approaches have been made by 11 cities and counties in 7 states and 1 province in Canada for surveys to be conducted in the near future.

We have been invited by the State Health Departments of Michigan and Ohio to undertake studies of their organization and administration, an opportunity which we shall welcome if the necessary funds for this purpose can be obtained.

In the fourth field of activity, that of propaganda for the advancement of the general cause of improved community health services, the committee has opened up during the year two very important possibilities of coöperative effort. The active interest of the U. S. Chamber of Commerce has been enlisted in this cause and three most helpful bulletins have been prepared in the Executive Office on *Prolonging Life by Coöperative Effort*, *Health and Community Prosperity*, and *The Health of the Business Man*, which have been printed by the Chamber and distributed to local chamber of commerce secretaries and to health officers throughout the country. Dr. Walker was also invited under the auspices of the Chamber to deliver a series of lectures on public health before the National School for Commercial and Trade Organization Executives. We believe that local health officers will find the movement thus actively fostered by the U. S. Chamber of Commerce of incalculable value to them in the future.

In conjunction with the American Child Health Association, continued coöperation has also been maintained with the General Federation of Women's Clubs in stimulating a health interest on the part of its constituent organizations.

A schedule of community health study was prepared and 3328 copies distributed to the local clubs, of which 93 schedules were actually filled out by clubs from 13 states. One month's free service was promised by the Committee on Administrative Practice as well as by the American Child Health Association to the state showing the largest proportion of communities participating, and this friendly competition was won by the State of Rhode Island.

The *Health Officers' News Letter* is issued monthly from the office of the committee and is now sent to all state health officers, to health

officers of cities having a population of over 30,000, and to all full-time county health officers.

BUDGET OF THE COMMITTEE

The total budget of the committee for the calendar year is estimated at \$42,000, balanced by an income of about \$19,000 from special grants and general retainers, and \$21,000 from payment for surveys and appraisals, leaving a \$2000 estimated deficit to be made up by the Association. For 1928 we look forward to a basic budget of \$48,000, with \$18,000 more needed if the state and rural surveys are to be undertaken.

The budget of the committee can conveniently be considered under 3 main heads. It includes first of all appraisals and surveys of local communities, which are normally self-supporting. Of the 15 city and country surveys in 1927, 14 were paid for—5 from municipal funds, 3 from funds of local voluntary agencies and 6 from funds of outside voluntary agencies interested in the local health work. This part of our budget takes care of itself and is likely soon to amount to about \$30,000 a year.

Special studies like the rural health survey and the state health survey must obviously be supported by special gifts and will only be undertaken if those gifts are forthcoming.

Finally, there is a basic and essential general service cost of the work of the committee which is and ought to be considerable. All the preliminary work of accumulating data for the various sub-committees, the preparation and revision of *Appraisal Forms*, the preparation of the *News Letter*, the conduct of the Information Service, the aid which must necessarily be furnished very frequently to health officers unable to pay for it—all these things involve a large part of the time of the staff and considerable expenditure for travelling, postage and printing which bring in no direct financial return. We have been able to carry this basic service cost during the past year through a grant of \$10,000 from the Metropolitan Life Insurance Company, a grant of \$7500 from the Milbank Fund, a retaining fee for consultation service of \$1000 from the Commonwealth Fund and a similar retaining fee of \$400 from the Department of Health of the City of Detroit. The indefinite continuation of grants from outside agencies is most unlikely and even with those now available the powers of the present field staff have been strained far beyond a wise and profitable limit. Dr. Walker has rendered to this committee a service of a rare and unusual character and his usefulness grows with the experience of every year. It would be the poorest policy to break down his health or let him slip out of our

hands to some more appreciative organization. We must give him additional assistance, which will require more money, not less.

There seem only 3 ways to finance this general service cost of the committee on a permanent basis: by grants from outside agencies, by grants from the Association, or by contributions from local health departments. Outside grants cannot be relied upon for an indefinite period and Association grants of large size are at present beyond our financial resources. It is really the health departments of the country which profit most directly and most immediately by the work of the committee. The logical source of support would seem to be contributions from these departments just as the source of support for the National Safety Council, which renders to the manufacturing industries a similar service, is found in the contributions of those same industries. If more cities would follow the example of Detroit and place in their annual budgets an item of \$100 to \$500 for consultant service from the Committee on Administrative Practice, our financial problem would be solved in the one really satisfactory way.

Babies' Hospital at New York Medical Center

CONSTRUCTION of the Babies' Hospital of the City of New York as one of the units of the Medical Center at 168th St. and Broadway has been begun. This is the eleventh unit to begin construction at the Medical Center since ground was first broken January 31, 1925. The Babies' Hospital will be a 12 story building occupying the site at 167th St. and Broadway. The plant based on the results of a study of babies' hospitals throughout the county will cost about one and a half million dollars, including building and equipment.

Joint Causes of Death*

ANY thorough study of causes of death certified by physicians upon death certificates brings one almost immediately to a consideration of two more causes of death certified for a single decedent. How should joint causes of death be treated?

Assuming for the moment that each death must be assigned to a single cause, how shall these single causes be selected? For several decades it has been customary in most countries to make these selections in accordance with sets of rules—rules not exactly the same in the several countries, but still rules more or less alike—so that the general tendency of such selection has been toward comparable vital statistics.

Regarding joint causes of death it should be pointed out that there are two goals to be kept in mind:

1. Accurate statistics for the United States
2. Accurate statistics for the United States comparable with accurate statistics for other countries

It is not hard to realize that the first goal might be attained, and yet the second goal might be still far away, if the various countries did not compile statistics in accordance with uniform rules of selection. To accomplish anything lasting toward international agreement in the selection of single causes from groups of two or more, representatives of the various countries must actually be convinced by arguments that each selection agreed to is the only proper selection. It will not be sufficient to obtain simply a vote of agreement, for unless the agreement is based on logical facts and definitely stated reasons, the agreement will not be lasting but will probably be superseded shortly by the first clear presentation of the facts of pathology, or clinical medicine, or public health importance. It might be well, therefore, to state a general principle for our guidance in working out this complex international problem:

1. We recognize that it is improbable that the nations will reach complete agreement in thought upon all points related to the reporting and classification and tabulation of births and deaths; and that without agreement in thought, action taken on the basis of a forced decision by a majority vote would retard rather than promote international accord in these matters.

Therefore our objects should be to attain by discussion as much agreement in

* Report of the committee, presented to the Vital Statistics Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 17, 1927

thought as possible, and, when such agreement in thought is not reached, to devise methods or procedures which will permit of the greatest degree of comparability in international vital statistics without doing violence to the convictions of the representatives of the various countries.

In the Bureau of the Census *Manual of the International List of Causes of Death* there are about 8,300 terms which have been used upon death certificates. Assuming that each term may be combined with every other, there are possible about 34 million combinations. Perhaps it would be more reasonable to assume that only one-half of the terms might enter into such combinations. In that case there would be possible about 8,600,000 combinations. To print even this smaller number would require 61 volumes of 1,000 pages each. The magnitude of such a work would be so stupendous that there is little wonder that in the second edition of the *Manual of Joint Causes of Death* (1925) an attempt was made to find a reasonably correct solution by grouping the terms, assuming that all terms in a group had equal weight. It is not claimed that this second edition should be regarded as the last word; many more subdivisions of titles are undoubtedly needed and many readjustments of terms under the various subdivisions; but it is hoped and believed that such changes will lead eventually to a manual of joint causes good enough for the careful compilation of mortality statistics to a degree of reasonable accuracy. It is too much to expect other countries to agree entirely to the selections made for these millions of combinations of causes. The most that we can possibly hope for is that other countries will give careful consideration to our joint cause manual and will publish similar manuals of their own. If such a course is generally followed an excellent start will have been made toward international discussions and toward international agreement.

In the meantime there exists a practical method of making the mortality statistics of the various countries much more comparable than at present. If each country would publish a contributory cause table, such as the Census Bureau did in 1918 and now has in press for 1925, it would be possible to see how joint causes of death are treated in each country and so to work out reasonably approximate figures for international comparison.

It seems to your committee, therefore, that the Vital Statistics Section ought to indorse strongly the following recommendations:

1. That each country publish manuals of causes of death similar to those already published by England and Wales and by the United States.
2. That each country publish a manual of joint causes of death to show how this problem is taken care of in each country.
3. That each country publish contributory cause tables showing the relation of the contributory causes to the principal causes of death.

Eventually, of course, it is to be hoped that the various countries will be able to agree in the main in the selection of single causes from groups of causes, but such a day is far in the future and we believe that more progress can be made toward comparability now, by emphasizing the value of contributory cause tables than by stressing the immediate need of uniform rules of selecting single causes.

The following lines recently received from Malcolm Fraser, Government Statistician of New Zealand, are very encouraging:

The copy of your *Manual of Joint Causes of Death*, which you so kindly sent me about two years ago, has proved of the greatest service in connection with the classification and tabulation of causes of death, and you will be interested to learn that we have adopted it in its entirety.

Revision of the Appraisal Form for City Health Work

WHEN the Committee on Administrative Practice approved the *Appraisal Form for City Health Work* in 1925, it also committed itself to continued study and periodic revision of the Form with the date of the first revision set for 1929. The sub-committee charged with the revision has already received many valuable suggestions which have been useful in its meetings. However, what the Committee needs now is specific information regarding the application of the existing appraisal form standards to local situations.

Requests have been made to health officers through the *News Letter* to apply the *Appraisal Form* to their particular communities and make this material available for committee guidance. Health officers, so reporting are participating directly in the establishment of standards of service. When he points out those items in which the standards are at considerable variance, the health officer renders a valuable service to the committee, as this information can only be obtained by the study of local conditions, such as was furnished in 1924 by a general survey of all cities.

Workers in other fields will also render assistance by furnishing specific information on standards and values, based upon actual experience and application of the *Appraisal Form*. The committee suggests that those engaged in administrative health work in cities apply the *Appraisal Form* to their local problems and advise the committee of the results.

Who Shall Teach Hygiene in College*

JESSE FEIRING WILLIAMS, M.D.

Teachers College, Columbia University, New York City, N. Y.

SINCE the close of the World War there has been a tremendous interest in health. The teaching of health in school and college has grown rapidly. The spur for this heightened interest has been the reported defects of drafted men, the malnutrition of European children, and the surveys of school children in the United States. This interest, expressed in the organization of departments of health education in schools and colleges, often supplants in the newer terminology that work carried on under the older title of hygiene.

Before this recent development of interest in health, most of the teaching of hygiene was conducted by departments of physical education. In some instances where a doctor of medicine was the head of the department, the hygiene was under medical direction, but often it was taught by those whose training was without any medical background.

This teaching of hygiene by experts in physical education has been varied in its worth. There are some samples of excellent college teaching of hygiene by this group; there are others that are totally incompetent and unsatisfactory.

A recent article in the *Nation's Health* argued that "physical directors are trained to teach exercises and games (and rightly so!) and not to teach preventive medicine or hygiene." The same article further contended that "a thorough biological background and a medical education with special reference to bacteriology and preventive medicine are absolutely essential for the well equipped instructor in hygiene."

Other things being equal, and due correction being made for the emphasis on pathology in the training of physicians, I believe it to be a fair assumption that a man trained in medicine *may* be a better teacher of hygiene than one trained only in physical education. In the long run, however, it is unwise to assume that there will be more successful teaching of hygiene by the former than by the latter. Such assumption leads to positive statements which err grossly in the light of the facts. There are quite as serious hazards when hygiene is taught by a

* This article was written by Dr. Williams in reply to the article, "Is Physical Education Related to Preventive Medicine?" by J. E. Rush, M.D., which was published in *The Nation's Health*, IX, 10:21 (Oct.), 1927.

physician as those presented when it is taught by the physical educator. This may not be apparent to some people because of their lack of information and perspective. One who knows physical education so inadequately that he confuses it with "physical culture" and is so unacquainted with the modern training given to specialists in physical education that he describes their training as consisting of "briefer courses in anatomy and physiology" the only subjects in the curriculum that could in any way be interpreted as having a bearing on hygiene," is hardly competent to judge of the relation that physical education bears to the subject of hygiene.

Graduate students who major in physical education in several universities have had courses in biology, physics, chemistry, physiology, anatomy, personal hygiene, educational hygiene, community hygiene, and some have had related courses in anthropology, bacteriology, eugenics, heredity, health examinations, and nutrition.

It is not too much to say that while the physical educator (not physical director) may not have all he requires as a needed background for the best teaching of health, it should also be noted that the physician lacks tremendously in his training. The average medical student gets about the same training in personal hygiene that theological students receive, and this according to a recent study by Storey amounts to what the chemists would call a "trace." The chief criticism of hygiene as taught by the usual physician is that it is academic. Here is a subject that deals essentially with problems of living: to select food properly, to use the body correctly, the rôle of work and rest in bodily activity, sleep, the present facts regarding prevention of disease, measures for developing immunity, personal problems in social adjustment, marriage and race problems, etc., etc. It is exceedingly ambitious for medical men to assume that they have a corner on such information.

One difficulty develops because medical men who have specialized in preventive medicine know so much of the subject that, like all teachers, they tend to develop the subject far beyond its usefulness. A student may learn to shoot a gun accurately without any of the theory involved in the chemistry of explosives or the tabulations of ballistics; indeed, one may become quite skillful in taking pictures and know very little about the science of optics. In like fashion, a student interested in living finely and well may learn how to meet his varied health problems without any lengthy discourse on Theobald Smith's formula on resistance or methods for correcting the crude rate in tabulation of vital statistics. Physicians with limited hygiene training are often of the opinion that prevention of disease should be the cardinal point in health courses. This is unproven. Indeed one study made shows that

students need and are interested in mental hygiene problems, adjustment to modern society, reproduction and mate seeking, physical activity, and nutritional problems. None of these is directly related to prevention of disease. The trouble with many teachers of "preventive medicine" is the academic character of what they teach. It is not a valid assumption that knowledge about disease is of any value *per se* in keeping people well. To say that the purpose of hygiene teaching is "to control sickness and lengthen the useful span of life" is to state a very narrow view. The purpose of hygiene teaching is to help people *to live at their best*. Moreover, ethics, decency and social relationships, comprise related aspects.

If medical men alone are to teach hygiene in colleges, we shall probably have as many errors in advice on how to live as we have now. We shall learn from the experts in preventive medicine who have "a thorough biological background" that development of the skeletal muscles does not strengthen the muscles of the visceral organs; we shall learn that there is an "athletic heart" in spite of McKenzie's work and the experience of expert cardiologists; and we shall learn that "athletic heart" is due to "inheritance or previous disease, or both."

It would appear from some observations and experience that the important factors, granted some acceptable training, to consider in selecting the teacher of hygiene are personal qualifications. The desirable qualities in a teacher of hygiene may be briefly stated in the following divisions:

1. He shall be scientific. Clearly he must not be a faddist. Belief in the efficacy of exercise as a prevention or cure for all things is as unsound as any similar proposal of sorcerer or magician. The faddist in preventive medicine today is subject to the same criticism.

2. He shall not be academically minded. Personal hygiene is a practical matter. The development of knowledge about health is to be evaluated in terms of its practical application. The Goddess Hygeia is a stern goddess.

3. He shall not be a formalist. The learning of mankind has an extended past. Ways of living and methods of procedure have been developed and have attained a certain rigidity of form. But learning how to live *may* be best taught not by traditional methods but by new and untried devices. Reliance upon formal means of education *may* be unwarranted. Experimental attitude, elasticity, and open-mindedness of spirit are very desirable.

Moreover, these qualities are essential if the doctor of medicine is to learn anything about health teaching. Nothing in his medical course prepares him adequately to act as teacher of personal hygiene. The work of teaching today has a technic and a method. It is not sufficient to assume that knowledge of certain material is the *sine qua non* for successful teaching. The operations of the mind in learning, the laws

of learning, the methods to insure greatest retention are not learned in medical schools. Because a physician deems a subject important is no guarantee that it will be so regarded by college students. One teaches only as another learns and the springs of learning are psychological and not medical fiat.

4. He must be a student of human problems. How to select a vocation and to meet vocational troubles, how to select a wife and to regard married life may offer more significant problems in hygiene teaching than a predetermined logical arrangement of eight lectures on immunity.

If it is remembered that the aim in teaching hygiene is to get people to live at their best, the necessity for these qualities will be clear.

In addition, it should be noted that the above discussion has not attempted to answer the question of the allocation of responsibility for health service, or health supervision, or physical education in the college. It has only considered health teaching.

The conclusions, then, are that physicians may be as ineffective as other persons in teaching health; that many persons trained in physical education are adequately helping students to live at their best and therefore teaching health effectively; that the qualities desirable in any teacher of health are a scientific attitude, freedom from the academic mind, open-mindedness, and understanding of life's problems.

Royal Sanitary Institute at Plymouth

THE Royal Sanitary Institute will hold its 39th Congress and Exhibition at Plymouth, July 16-21 at the invitation of the Town Council of Plymouth. The meeting is held to stimulate interest in all public health matters and offer an opportunity to health authorities and to representatives of professional and industrial organizations to discuss problems relating to public health administration. Sanitarians from many countries will be present to discuss the most recent advances in preventive medicine and sanitary science.

A health exhibition illustrating municipal sanitation and domestic health and comfort will be arranged for the delegates.

Any members or Fellows of the A. P. H. A. who expect to be in England at the time of the Congress are asked to communicate with Homer N. Calver, Executive Secretary, 370 Seventh Avenue, New York, N. Y.

Swimming Pools and Other Public Bathing Places*

A COMMITTEE on Swimming Pools was appointed by the Sanitary Engineering Section of the American Public Health Association at the Chicago Meeting in December, 1918. At the first Conference of State Sanitary Engineers at Washington in May, 1920, a similar committee was appointed, two of the three members being also members of the A. P. H. A. committee. These committees have been continued from year to year and since the personnel has always been practically identical, the two separate committees have worked together as one body. At the 1925 meetings the Conference and the Sanitary Engineering Section each voted to unite the two separate committees into a joint committee representing both organizations.

The work of these committees has been greatly facilitated by the continued reappointment of its members. Stephen DeM. Gage, at present chairman of the Joint Committee, has served continuously as chairman of the Conference committee and has been continuously a member of the A. P. H. A. committee since these committees were instituted. George W. Simons, Jr. has also served continuously on both committees with the exception of 1926, and was chairman of the A. P. H. A. committee from its inception until it was merged in the Joint Committee. Harry F. Ferguson has served continuously since 1920. E. S. Tisdale has served continuously since 1922, and C. G. Gillespie has served as a member since 1920 with the exception of the two years 1920-1922. Other present or former members of these committees have been J. W. M. Bunker, 1918-1919, M. C. Whipple, 1918-1920, M. F. Hasbrouck, 1919-1920, Ralph Hilscher, 1920-1923, H. V. Pedersen, 1924-1926, Jack J. Hinman, Jr. 1925-1927, Howard W. Green, 1925-1926, and Richard Messer 1925-1927.

At the time when these committees were instituted the practice as to construction, equipment, and operation of swimming pools varied widely, and only two states, California and Florida, had made any effort to put bathing places under the supervision of the public health authorities. The first work of the committees, therefore, was to collect and disseminate information as to conditions and methods at pools in dif-

* Report of the Joint Committee on Bathing Places of the A. P. H. A. and the Conference of State Sanitary Engineers, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, Oct. 18, 1927.

ferent parts of the country. Early in its history the committee met the challenge that swimming pool sanitation was not a public health problem by collecting and presenting statistics to show that a considerable number of epidemics of different diseases had been caused by improperly operated swimming pools or by the indiscriminate use of incompletely sterilized bathing suits and towels. In other reports the committee has presented data on the methods of laundering suits and towels, on methods of disinfection of pool waters, on methods and equipment for the prevention of accidents, as well as on a variety of other related topics.

During recent years the committee has received repeated requests to prepare a standard code which might be used as a basis for regulations for the sanitary control of pools and other bathing places. In 1923 both committees presented tentative standards for the physical, chemical, and bacterial quality of swimming pool waters together with certain operating regulations aimed to facilitate the maintenance of such standards. Although these standards have not been formally adopted by either of the organizations to which they were presented, they have become quite generally accepted and as a whole or in part have been incorporated into the sanitary codes of a number of different states and municipalities. In its report to the Conference of State Sanitary Engineers in May, 1926, the Joint Committee recommended tentative standards for the design, construction, and equipment of swimming pools, and in its report to the Public Health Engineering Section (formerly the Sanitary Engineering Section) in the fall of the same year incorporated with these standards the tentative standards of water quality which it had previously presented in 1923. Both organizations after full discussion referred the reports back to the committee with instructions to make such minor corrections and revisions as might be advisable and present a final report on standards for adoption at the 1927 meetings.

The standards as presented represent not only the experience of the various members of the committee, but the consensus of opinion of a large number of sanitary officials and swimming pool operators throughout the country. Swimming pools and other bathing places are now being studied intensively by health officials throughout the country and with advanced knowledge of practical working conditions and new developments in equipment and operating methods, changes in standards of this kind become inevitable. If by setting up standards which are impracticable, or which are either too strict or too lenient our committee has paved the way for better standards and bet-

ter conditions, we may well feel that we have advanced the cause of sanitary progress.

The report to the Public Health Engineering Section, with the standards presented at that time, was published in full in the *American Journal of Public Health* for December, 1926, and reprints of the same have been distributed quite widely. Your committee has had much correspondence with various persons interested in swimming pool sanitation with reference to various sections of these standards, and it appears that no radical changes are advisable. A few minor changes have been made in the wording of certain of the sections in order to promote clarity.

A brief historical preface, together with an appendix * giving illustrations of the method of computing the bathing loads on typical pools, has been prepared for publication with the standards which are finally adopted.

Your committee now recommends the adoption of the standards as printed with the following changes.

Section VI. Add following sentence at the end of section. "An illustration of the computation of the safe bathing load for typical pools is given in the appendix."[†]

Section XVIII, E. Change wording of section to read as follows. "Sterilization of clear water may be obtained by exposure in thin films to ultra-violet rays. It is claimed by the proponents of this method of swimming pool disinfection that the water after treatment contains a residual disinfecting agent whose action is similar in effect to that which is obtained by the use of a slight excess of chlorine either as gas or in solution. So far as the committee has been able to determine no conclusive evidence has been produced to establish this claim. Until such evidence is produced it must be assumed that disinfection by this process proceeds according to the law of purification by consecutive dilution and is subject to the limitations imposed by that law. On this assumption there is never any definite and determinable amount of disinfectant in the pool water to act on infectious material which may be discharged by bathers during the bathing period at the time when such material is most dangerous. In a few cases satisfactory control of the bacterial content of pool water has been reported by the use of ultra-violet disinfection alone. In a considerable number of instances, however, it has been found advisable to reinforce or supplement the ultra-violet treatment by treatment of the pool with chlorine or hypochlorites. Until reliable evidence is produced that ultra-violet treatment will cause the pool water to contain a sufficient residual disinfectant to take care of casual contamination and until methods have been devised by which any such residual disinfecting action can be readily determined and controlled, the committee cannot recommend the use of violet ray apparatus alone for disinfection of any pool where the bathing load is high or where large temporary loads are likely to occur."

Section XXIV, A. Change minimum excess chlorine required from 0.1 p.p.m. to 0.2 p.p.m., making section read as follows. "Whenever chlorine, calcium hypochlorite or other chlorine compounds are used for swimming pool disinfection, the

* See next page.

amount of available or excess chlorine in the water at all times when the pool is in use shall not be less than 0.2 p.p.m. or more than 0.5 p.p.m."

Section XXV. Add a new paragraph to read as follows: "D. All chemical and bacterial analyses should be made in accordance with the procedures recommended in the *Standard Methods of Water Analysis* of the A. P. H. A. in so far as those methods are applicable to swimming pool waters."

Section XXVII, B. Reword this section to read as follows. "At any pool where the addition of disinfectant is not continuous during the bathing period the total number of persons permitted to use the pool between any two consecutive disinfections shall not exceed 7 persons for each 1,000 gallons of water in the pool and each disinfection shall be sufficient to insure that the bacterial quality of the water shall conform to the limits stated in Section XXV of these standards."

An illustration of the computation of the limiting bathing load is given in the appendix.

APPENDIX I.

ILLUSTRATION OF COMPUTATION OF BATHING LOAD LIMITS FOR A TYPICAL POOL IN ACCORDANCE WITH REQUIREMENTS STATED IN CHAPTERS VI AND XXVII.

Section VI. Estimation of number of bathers who may safely be permitted to use a pool at one time.

Case 1. Assume a pool 60 feet x 20 feet in area, minimum depth 5 feet, capacity 50,000 gallons. No diving board or other specified diving area. Entire area 1,200 square feet is swimming area. Allowing 27 square feet per person (VI, C.) the maximum safe load at one time is $1200 \div 27 = 44$ persons.

Case 2. Assume same pool as Case 1 with a diving board projecting 10 feet at center of one end of pool. As pool is 20 feet wide and 10 feet radius from end of board is reserved for diving, diving area is 400 square feet. Safe limit for this area is 12 persons. (VI, B.) Swimming area is reduced to 800 square feet in which maximum safe load is $800 \div 27 = 30$ persons. Total maximum safe load at one time under these conditions is $30 + 12 = 42$ persons.

Case 3. Assume a large pool, 18,000 square feet area, deep water with one diving tower in center, water depth less than 5 feet on 75 per cent of pool area. The safe load at one time should be computed separately for each of these zones. Diving area may be computed as a circle of 14-foot radius measured from center of tower, with simultaneous diving in each of four quadrants. Diving area = 616 square feet with maximum safe load of 48 persons. Shallow or wading area = 75 per cent = 13,500 square feet in which the maximum safe load is $13,500 \div 10 = 1,350$ persons at one time. Swimming area is 3,994 square feet in which maximum safe load is estimated at $3,994 \div 27 = 148$ persons at one time. The maximum safe load at one time in this pool may be estimated as $48 + 1,350 + 148 = 1,546$ persons.

Section XXVII. Estimation of permissible maximum bathing load limits in relation to water replacement and disinfection.

Case 4. Fill and Draw pools with intermittent disinfection

Assume a pool of 50,000 gallons. Under XXVII, A, $50 \times 20 = 1,000$ persons may use the pool before it must be emptied, cleaned and refilled. Assuming the water supply conforms to the requirements of Section XXV, $50 \times 7 = 350$ persons may use pool after filling before disinfection is required. XXVII, B. After complete disinfection 350 additional persons may use pool before a second disinfection is required. After second complete disinfection 300 additional persons may use pool at which time 1,000 persons will have used the pool and the water must be replaced.

Case 5. Flowing through and recirculation pools

Assume a pool of 50,000 gallons with water being withdrawn and replaced with new or filtered water at a rate of 2,000 gallons per hour. Under XXVII, A, the volume of new clean water being added would be sufficient for $2 \times 20 = 40$ persons per hour or 400 persons during a 10-hour bathing day. If the flowing through or recirculation were continued throughout the entire 24 hours, with bathing limited to 10 hours, there would be an accumulation of $2,000 \times 14 = 28,000$ gallons of clean water during the non-bathing interval or a sufficient amount for $28 \times 20 = 560$ additional persons. The total load on this pool would therefore be limited to $400 + 560 = 960$ persons per day by the clean water requirements.

If disinfection were intermittent the number of persons using this pool between any two consecutive complete disinfections would be 350 as in Case 4. The maximum usage which could be made of this pool in one day under the stated conditions with intermittent disinfection would be as follows: After complete disinfection in the morning 350 persons could use the pool. A second complete disinfection could then be given the pool and an additional 350 persons permitted to use pool. A third complete disinfection could then be given and an additional 260 persons be permitted to use the pool before the volume load limit of 960 persons was obtained.

With continuous disinfection it must be assumed that the pool is in a state of complete disinfection at all times while the excess chlorine is within the limits prescribed in XXIV, A. Under these conditions the rate of water replacement would govern as described above, and 960 persons per day could use the pool.

It will be noted that if the maximum-safe-load-at-one-time rule were strictly observed it would require over 21 consecutive classes of 44 persons each or an average of one class every 28 minutes to attain this maximum in one day. The committee has no sufficient information on pools operated with excessively high bathing loads, and it is possible that the required chlorine content could not be maintained under the extreme conditions stated. It seems probable, however, that if classes were kept within the safety limits specified and the chlorine content maintained within the prescribed limits, the other stated load limits would be unlikely to be exceeded in ordinary practice.

Social Workers To Meet In Paris

TWENTY-ONE nations will be represented at the First World Congress of Social Workers to be held in Paris, July 8-13, 1928. John A. Kingsbury, secretary of the Milbank Memorial Fund who attended a meeting of the organization committee of the Congress in Prague estimates that more than 1000 American delegates will attend the Congress to be held under the patronage of the President of France. The participating groups include the International Child Welfare Congress, International Housing and Town Planning Congress, International Congress of Public and Private Welfare and International Conference of Social Work.

Disposal of Sewage and Industrial Wastes*

THE COMMITTEE'S activities this year have taken the form of brief papers on subjects of current interest, together with the completion of the Definitions, as follows:

Almon L. Fales, Boston, Mass., writes on Progress in the Control of Pollution by Industrial Wastes

W. L. Stevenson, Harrisburg, Pa., on Waterway Sanitation

C. B. Hoover, Columbus, O., on Sludge Disposal

C. M. Baker, Madison, Wis., (although not a member of the Committee) has kindly prepared a paper on The Stream Pollution Problem, showing coöperation in the state of Wisconsin.

Kenneth Allen, New York, N. Y., has completed the Definitions of Terms Used in Sewerage and Sewage Disposal Practice.

Ten years ago a list of 97 definitions was presented by a committee of this section of which George S. Webster was chairman. Mr. Allen was an active member of that committee.

In 1924 a committee of this section was given the task of "Rewriting the Definitions." A reprint of the previous list was sent out to all members of the section and numerous replies were received. Similar action was also secured from the Sanitary Engineering Division, American Society of Civil Engineers. Our committee completed its report and presented it at the section meeting in Detroit 3 years ago. This list consisted of 321 titles arranged dictionary style, to which was appended a Schematic Outline broadly classified under 3 heads:

I. Liquid and Water Carried Wastes flowing in Sewers and Drains

II. The Collecting System

III. Disposal

The A. S. C. E. committee did not present any definitions at that time and its subsequent work was interrupted by the regrettable death of its chairman, Professor George C. Whipple.

This work was later taken up by W. W. Horner of St. Louis, and a committee of the Sanitary Engineering Division, A. S. C. E. Debatable definitions were submitted to many well known engineers and the mass of data was then referred to Mr. Allen, who, from his association with the original committee, his membership in both the societies concerned and his constant and close contact with the subject, was deemed espe-

* Report of the committee, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

cially fitted to harmonize the definitions and to prepare the final draught which is herewith submitted. It now consists of 310 titles and a total of 332 definitions.

A duplicate of these definitions was presented by Mr. Horner and his committee at the A. S. C. E. meeting at Columbus, O., on October 13, 1927.

The committee trusts that it has fulfilled its assignment and herewith submits the above mentioned papers and the "Definitions" as its report for the year 1927.

JOHN F. SKINNER, *Chairman*

ALMON L. FALES

W. L. STEVENSON

Definitions of Terms

Sanitary Engineering Division,
of the American Society of Civil Engineers.

Gentlemen:

Your Committee on Definitions of Terms Used in Sewerage and Sewage Disposal Practice, begs leave to submit its final report as follows:

This committee was first constituted in 1924, under the chairmanship of the late Professor George C. Whipple. Professor Whipple's death came in the fall of 1924, shortly after the submission of a tentative progress report.

At this time, a similar committee of the Sanitary Engineering Section of the American Public Health Association, under the chairmanship of John F. Skinner, presented a report to that section of the A. P. H. A. Both reports were received and the respective organizations instructed their committees thereafter to act jointly until such time as a joint report could be presented for the approval of each society.

In the summer of 1925, the committee of the A. S. C. E. was reconstituted, to consist of Paul Hansen, Theodore Horton, and W. W. Horner, *Chairman*. In 1926 and 1927, the committee has consisted of Paul Hansen, E. Sherman Chase, and W. W. Horner, *Chairman*. During the years 1925, 1926, and 1927, the personnel of the A. P. H. A. committee has also varied, but the chairmanship of Mr. Skinner has been continuous.

In the summer of 1925, the two committees reached an agreement on a plan of joint operation, and on October 19 and 20, a joint conference was held in St. Louis, between some of the members of each committee. At this time all previous lists of definitions were canvassed and the beginning of a new list made up. The list prepared at this meeting was sent out to the members of each committee and was modified quite appreciably by correspondence during the fall of 1925. Agreement was reached with regard to the definitions of the greater number of terms, but there remained a considerable list with regard to which radical differences developed.

In the fall of 1926, the joint committee expanded its membership temporarily by sending to approximately one hundred sanitary engineers, definitions in the alternate of some seventy terms, and received in turn, definite expressions of opinion, from about thirty-five men. With the aid of this assistance, the committee reached conclusions on about two-thirds of the disputed terms.

The work of preparing the final list was then assigned to Kenneth Allen, to whom were furnished full statements covering the differences of opinion still existing. Mr. Allen submitted many of these questions to selected groups of engineers, and arrived at his own conclusions which were again presented to the joint committees for criticism.

Some further revision resulted and finally in September, 1927, the chairman of the two committees reached an agreement that little improvement could be expected by further discussion and recommended the submission of the report in its then existing form for adoption to the two organizations. This action having met with the approval of the membership of the two committees, your committee of the Sanitary Engineering Division of the A. S. C. E. presents the list of definitions herewith,* recommends that it be accepted by the division, and that it be presented for publication by the society.

The committee further requests that it be discharged and that a record be made of the desirability of the appointment of another committee on the same subject about five years hence.

W. W. HORNER, *Chairman*,
PAUL HANSEN,
E. SHERMAN CHASE.

* The Definition of Terms Used in Sewage Disposal Practice, which is the Report of the Joint Committee of the A. P. H. A. and the A. S. C. E., will be published as a manual by the A. S. C. E. Members of the Public Health Engineering Section of the A. P. H. A. will receive copies. Upon request the manual will be available to other members of the Association.

Medical Society of the County of New York

PREVENTION of disease is the general subject of a course of free lectures being given by the Medical Society of the County of New York, Public Health Education Committee, at the New York Academy of Medicine, 1 East 103 Street, New York, N. Y. These lectures, given on the second and fourth Thursday of each month at 4:00 p. m., started on January 12, and will continue until April 26. This course which the public is urged to attend, is given with the full coöperation of the New York Academy of Medicine.

Some of the lecturers on this program are: Beatrice Hinkle, M.D.; George K. Pratt, M.D.; Herbert B. Wilcox, M.D.; Matthias Nicoll, Jr., M.D., Commissioner of Health, New York State; Henry James, M.D.; Richard Kovacs, M.D.; Madge C. L. McGuinness, M.D.; Edward C. Titus, M.D.; Shirley W. Wynne, M.D., Deputy Commissioner of Health, New York City; Colonel Robert Starr Allyn; Harry Hopkins, New York Tuberculosis and Health Association; Aaron S. Blumgarten, M.D.; Rosalie S. Morton, M.D.

On March 22, the lecture will be on "Laboratories in the Diagnosis and Prevention of Disease." Anna W. Williams, M.D., will preside at this session and the lecturers will be Frederic E. Sondern, M.D.; M. C. Schroeder, M.D. and William H. Park, M.D., Director of Laboratories, Department of Health of New York City.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

UNITED STATES PUBLIC HEALTH SERVICE

ANNUAL REPORT OF THE SURGEON GENERAL

THE ANNUAL report of the Surgeon General is always of great interest. For the past two or three years, it has been more complete than ever before, since agreements have been entered into, by means of which we are kept in constant touch with health conditions throughout the world. These agreements also greatly assist our Service in preventing the introduction of contagious diseases into this country.

The two factors which best indicate general conditions for the country, are the total death rate, and the death rate of infants under one year of age per 1,000 live births. For 1926, the death rate for 28 states was 12.1 per 1,000 population, slightly higher than for 1925, apparently as the result of the large number of deaths from respiratory diseases. The infant death rate for 28 states was 72.8, also a little higher than the rate for 1925; but only 10 years ago, it was approximately 100 per 1,000 live births. There was a general decline in the death rate from most diseases. In Europe there was quite a severe epidemic of influenza, which fortunately did not reach this country, and in Asia there was a large amount of cholera, that country still being the home and hotbed of the disease.

In 1916, the late Dr. Guit  ras pointed out that the greatest danger of the tropics to other countries was bubonic plague, and this warning was repeated in a report of the Surgeon General several years later. During 1926, it has shown a decreased prevalence, but is still one of the greatest menaces which we have to face. Approximately nine-tenths of the cases for the year have been in India.

All of us can remember when the name yellow fever made us shudder. Lately it has been confined to one small part of Africa, and during 1926 a single case was reported from Brazil. No case of cholera, yellow fever, or plague gained entrance to the United States during the year,

though 2 cases of plague, 17 cases of smallpox and 2 cases of leprosy were detected at the port of entrance, but got no further. Plague still exists among rats and ground squirrels in certain parts of California, and compels constant watchfulness.

Smallpox decreased, but it will astonish many to know that more than 30,000 cases were reported from 41 states. We cannot but believe that physicians depend too much upon a single vaccination. Revaccination should be practiced at regular intervals in childhood, and whenever a person is exposed to the disease. If a successful take does not result, the operation is painless; if a take does occur, it is evident that the patient needed it. Nothing in connection with medical science is better known than the fact that vaccination with revaccination will obliterate smallpox.

The examination of incoming vessels continues. Twenty thousand, two hundred and eighty-four vessels, with 820,793 passengers and 1,140,922 seamen were inspected at domestic ports, and a large number at insular ports. One of our best safeguards is the inspection at foreign ports of vessels and passengers bound for the United States. Five thousand, nine hundred and fifty-four vessels, 424,172 passengers and 272,873 seamen have been inspected for the year in this service. Seven thousand, one hundred and sixteen vessels were fumigated on account of disease or for the destruction of rodents, and more than 31,000 rats were found, 18,000 of which were examined for plague.

Perhaps the most discouraging feature of the report is the high prevalence of venereal diseases among patients treated by officers of the Service. This has averaged 20 per cent for many years, and for 1926, was 17.

Apart from the purely medical subjects reported upon, the most important features are two conventions, one held in Paris, attended by the representatives of 60 governments, to revise and improve existing treaties regulating maritime commerce, and the other, a conference held in Washington of the Pan American Governments, for the formulation of a constructive program in matters pertaining to public health and sanitation.

ALASTRIM A FORM OF SMALLPOX

IT HAS been widely held that the general adoption of vaccination against smallpox has led to a modification of the disease, so that mild cases now occur, which otherwise would have been severe. Difficulties in diagnosis have arisen owing to this fact.

Others have held that there are two types of smallpox; one mild and one severe, and numerous theories have been advanced to account for

the differences between the two. The matter has been quite fully discussed by Dr. Chapin,¹ who rejected many of the theories which have been advanced, and who holds that there is a clear distinction between the severe form and the mild form, pointing out that the two types have existed together, and that it has been impossible to stamp out the mild form, in spite of rigorous isolation and vaccination. Furthermore the two types breed true. In the United States it has prevailed for upward of thirty years, while the classical and severe type has been comparatively rare. England has had a number of outbreaks of both types during the past twenty-five years.

More recently our attention has been called to a disease known as "alastrim," which also goes under the following names: amaas, varicoid, varicella, Kaffir milk pox, Sanaga pox, the Australian disease, Cuban itch, Philippine itch, etc. This has been held by some to be a distinct disease, though our Public Health Service has consistently maintained that it was a type of smallpox. A long series of experiments just reported by our Public Health Service has demonstrated that a "definite cross-immunity exists between alastrim and mild smallpox," as well as between alastrim and vaccine virus.

A number of experiments have been carried out on monkeys and rabbits, and the conclusion seems inevitable that alastrim is a type of smallpox, and should be treated as such.

THE NUTRITIVE VALUE OF OLEOMARGARINE

A STATEMENT concerning the food value of oleomargarine seems necessary in view of what was said in the abstract section of our issue of October, 1927, in which it was stated: "Oleomargarine is of no value for any nutritive purpose," this opinion apparently having been based upon a previous statement that "oleomargarine is practically devoid of vitamins." These pronouncements are obviously not supported by the fact.

Broadly speaking, there are two types of oleomargarine on the market, one which is made largely from animal fats, and one from vegetable fats, such as cocoanut oil, cotton seed oil, etc. It is therefore inaccurate to speak of oleomargarine without stating which type is referred to. However, it can be said with certainty that all oleomargarines have a food value equal to that of their constituents. The nutritive value of a substance is not entirely dependent upon its vitamin content. If we accept the vitamin content as a standard, we shall be obliged to dis-

card many of our most valuable food stuffs, such as wheat flour, sugar, lard, etc.

Rosenau¹ correctly says, "Since all of the ingredients are in themselves useful foods, the wholesomeness and nutritive value of the finished product is beyond question." He further states the well-known fact that oleo oil is a recognized source of vitamin A; and various studies by men such as Osborne and Mendel, Halliburton and Drummond, Steenbock and his associates, and a number of other investigators, have shown that the animal fats from which oleo oil is made, as well as the oil itself, contain varying, but often large amounts of vitamin A. Steenbock,² Hoagland and Snider,³ and others have shown that the color of the fat and its vitamin content bear some relation to each other, those which are most pigmented being generally the richest in vitamin A. Osborne and Mendel have shown that the oleo oil contains practically all of the vitamin A present in the beef fat from which it was made, leaving very little in the oleo stearin, which is used chiefly in the preparation of baking compounds. The "yellow oil" prepared from fats derived from grass-fed cattle, generally runs highest in vitamin A.

An examination of twenty-four specimens of oleo oil collected from various parts of the United States, from Denver and Fort Worth on the west and south, St. Paul on the north, and New York on the east, have shown that the yellow oils are much the richest in vitamin A, a ration containing 10 per cent of this grade frequently producing normal or very nearly normal growth in rats.⁴

Some oleomargarines contain butter fat, which is intentionally added, and it is the general practice to churn oleomargarines in milk. Recently some manufacturers have been adding vitamin A. The process is said to be a trade secret, but it has been suggested that cod liver oil or other substances notably rich in vitamin A are used. The fact is that at least one of these products, although made from vegetable fats, has been constantly improving, and recently has shown results in experimental animals better than those produced by butter.⁵ The Medical Research Council⁶ of England rates oleomargarine made from animal fats other than lard, from + to + + . Cod liver oil and some other fish oils very rich in vitamin A are rated + + + .

There is no question that butter is one of our richest and most dependable sources of vitamin A, yet, without known exception, authors state that the content is variable and apt to be very deficient in the butters produced in late winter and early spring. It has been shown that cows can be maintained in apparently good health for long periods on a diet practically devoid of vitamin A, and produce milk, and consequently butter, which is very deficient in this substance.

Numerous experiments have shown that oleomargarine is equally as digestible as butter, is palatable, and keeps much better than the poorer grades of butter. The animal fats from which it is made are subject to federal meat inspection, and only the fats from animals which have been passed by our government officers can be used in its preparation. We are therefore assured of its entire wholesomeness. On the other hand, any dirt, rancidity or extraneous flavors make the fat unsuitable for the manufacture of oleomargarine.

In the manufacture of the vegetable fat oleomargarines, which do not come under the Meat Inspection Service, pasteurization of the milk and other dairy products used is regularly practiced.¹ The late Professor Harrington,² of Harvard University, said that oleomargarine has been misrepresented to a greater extent than probably any other article of food, and pointed out that it was made only from the cleanest materials and in the cleanest possible manner; that it was equally as wholesome as butter, and that when sold for what it is, and at the proper price, it brought into the dietary of those who could not afford the better grades of butter, an important food fat. We know of nothing which justifies a modification of this statement. The increased use of the vegetable oils and our newer knowledge of the importance of vitamins, make it necessary to supplement margarines with good whole milk, or other vitamin bearing foods. If the practice of adding vitamins, above mentioned, becomes general, even this precaution will not be so urgent.

ASSOCIATION NEWS

CENTRAL PROGRAM COMMITTEE

THE first meeting of the Central Program Committee to arrange for the scientific program of the Chicago Annual Meeting, to be held October 15 to 19, will be held February 11. All members and Fellows of the Association who expect to offer papers for the Chicago program are urged to communicate without delay with their respective section chairmen or with the Executive Secretary of the Association, Homer N. Calver, 370 Seventh Avenue, New York, N. Y.

In past years it has been necessary to close the program two months or more before the Annual Meeting and as a result it has been impossible to accept valuable papers offered at the last moment.

The Program Committee is interested in having contributions from new authors and accounts of new work which has not been reported elsewhere. The presentation of papers is limited to fifteen minutes (3000 to 5000 words) and each author is expected to furnish a copy of his manuscript, or an abstract of it, in advance of the meeting.

The Hotel Stevens has been selected as headquarters for the meeting and according to present plans all sessions and exhibits will be held in this hotel.

Five hundred rooms and baths at \$3.50 for single occupancy have been reserved for members and Fellows of the Association. Those who make their reservations too late to secure one of these rooms can be assured of accommodations at \$4.00 per day. In making reservations for the purpose of the meeting it is essential to indicate the date of arrival. Accommodations will be assured if those making the reservations will state that they are members of the American Public Health Association

DR. WALLACE WITH THE A P H A

JAMES W. WALLACE, M. D., Deputy Health Commissioner of Iowa has been appointed Associate Field Director for the Committee on Administra-

James W. Wallace, M D

tive Practice, and will assume his duties with the Association on February 1. He will be engaged in making surveys and appraisals of health work.

Dr. Wallace has had extensive experience in public health work. He obtained his M. D. degree from Queens University, Toronto, later taking graduate work at the Rush Medical College, University of Chicago and the Mayo Clinic, Rochester, Minn., and the Crile Clinic, Cleveland, O. He obtained a Certificate of Public Health from Massachusetts Institute of Technology and Harvard University.

Dr. Wallace served for 4 years with the University Hospital Service in Egypt, England and France, and during the World War was awarded the Mons

Medal for service with the Canadian Forces.

He has been associated with the International Health Board, having been appointed to the state health programs conducted by the Board in North Carolina, Alabama and Virginia. Before being appointed Deputy Health Commissioner of Iowa, which position he has occupied for the last 2 years, he was director of rural health organization of Iowa and was State Epidemiologist in Utah. His outstanding piece of work in Utah was the extensive goiter survey.

COMMITTEE ON ADMINISTRATIVE PRACTICE

THE public presentation of the report of the St. Louis health and hospital survey, made by the Field Staff of the Committee on Administrative Practice, was made to the local committee in St. Louis on January 9. Public meetings were also held at the Chamber of Commerce and before the medical society for the presentation of the public and professional aspects of the study. Haven Emerson, M.D., as consultant, presented the report dealing with the facilities for the care of the sick.

The annual health examination of the Child Health Demonstration Areas of the Commonwealth Fund has been begun by the appraisal of the services in the city of Fargo, N. D. Studies of Athens and Clarke County, Ga., and Rutherford County, Tenn., the two southern demonstration areas, will be carried on during February.

The Field Staff of the Committee on Administrative Practice will spend some time during February in Montreal where it has been called in as consultant in connection with a survey and appraisal of health activities being carried on by the Montreal Anti-Tuberculosis and General Health League in coöperation with the Health Officer.

Two important sub-committees of the

Committee on Administrative Practice met during January. The Sub-committee on Analysis of Public Health Procedure, Allen W. Freeman, M. D., *Chairman*, has as its function the analysis of demonstrated values of various community health activities in terms of actual health saving—a problem of enormous difficulty, but the solution of which will alone give us the ultimately sound basis for the standards and the appraisals now necessarily grounded in the main on group judgment and empirical experience. The personnel of this committee includes: Henry F. Vaughan, D.P.H., Geo. T. Palmer, D.P.H., Geo. C. Ruhland, M.D., Lowell J. Reed, Ph.D., Edgar Sydenstricker.

The Sub-committee on Model Health Ordinances spent two days in a discussion of essential items to be written into the basic legislation of a health department. This committee does not expect to put its material into standard legal form. It contemplates an outline of those items which should be put into the basic laws and those which should be written into a sanitary code or other rules or regulations adopted by the health department. Henry F. Vaughan, D.P.H., as chairman, is assisted by Haven Emerson, M.D., Huntington Williams, M.D., and James A. Tobey, Dr. P.H., in this work.

A survey of city and county health activities in Spartanburg, S. C., was completed in January by C. St. Clair Drake, M. D., Field Associate, Committee on Administrative Practice.

THE Local Committee for the 57th Annual Meeting of the Association, to be held in Chicago the week of October 15, 1928, is being organized, with Professor E. O. Jordan as Chairman, and Arthur E. Gorman, Secretary.

THE committee authorized to direct a census of public health workers has been appointed. It is composed of Ar-

thur E. Gorman, C. E. Turner, John F. Norton, George H. Van Buren and John L. Rice. The first meeting of the committee will be held in the Executive Offices February 10.

THE second public health conference called by the American Medical Association will be held March 30-31 at A. M. A. headquarters in Chicago. The A. P. H. A. has been invited to be represented at this conference.

WILMER R. Batt, M.D., Field Representative for the Committee on Registration Area of the A. P. H. A. is now working in Texas, with headquarters in Austin.

DEATH OF PROFESSOR JAMES O. JORDAN

PROFESSOR James O. Jordan, Milk Inspector of the Boston Health Department, died on January 6, 1928, at the New England Baptist Hospital.

Professor Jordan was born in Lisbon, Me., May 26, 1864. After graduation from the College of Pharmacy, he was appointed, in 1884, a chemist in the Bureau of Milk Inspection of Boston. He held this position for 21 years and was then promoted to the position of Milk Inspector. For several years he taught at the college and became a life member of its Corporation. He was Secretary of the Section on Food, Drugs and Nutrition of the American Public Health Association, a member of the Executive Committee of the Massachusetts Association of Boards of Health, a member of the Boston Medical Milk Commission, a member of the Massachusetts Milk Inspectors Association, as well as a member of several other associations, and belonged to the Fraternal Order of Elks.

Professor Jordan devoted much of his life to the enforcement of milk laws and was a pioneer in the cause of milk legislation. He was the author of many papers on the different phases of the milk problem and is widely known for his work.

In his service to the section he was dependable, capable and faithful. He was quiet and unassuming in manner. In one of his last letters he recommended that committees be made small in membership for effective work, and he heartily endorsed the idea that we want "facts, not opinions." He will be missed from the work of the Association. His long affiliation with us and his close identity with the work of the Food and Drugs Section as Secretary, since its establishment in 1916, gave him an intimacy with the work and an acquaintance with details that were highly valuable to the successive chairmen. An old timer has passed on. The cause of public health has lost one of its best workers.

LETTER TO THE EDITOR

TO THE EDITOR:

In promoting vaccination, and more recently, in promoting immunization against diphtheria, health officers have frequently fallen into the blunder that Jenner himself committed when he claimed for the prophylactic treatment much more than facts would warrant.

It seems to me that the progress of the movement to adopt immunization as routine practice is hindered rather than helped by such extreme statements, since it leaves the practice open to valid criticism on the part of opponents, who need only a few dramatic exceptions to discredit the principles advocated by health officers. I am writing you now because I have just noted an exceptionally bald statement from the health department of one of our better cities:

Every child after the age of six months should be protected against diphtheria. The treatments are safe. They cannot possibly do the child harm, and once the immunity against diphtheria has been developed by means of toxin-antitoxin, it insures an absolute protection for life.

One can accept the conclusions—that is, the advisability of immunizing every

child after the age of six months—but is it sound public education to rest the case on the assertions that follow? When Dr. Stewart in Minnesota, or some other student, points out the dangers in allergic reactions, the anti-vivisectionists and anti-vaccinationists have enough material to discredit the whole program. My answer would be, not the silencing of Dr. Stewart, but the challenging of the reckless claims made by public health officers. The health officer or the physician who administers toxin-antitoxin ought to know that such treatments “are safe”; but he ought to know also that they *can* do the child harm under certain conditions, although the careful technician knows how to recognize the danger in most cases. Moreover, it is utter non-

sense to talk about insuring *absolute* protection, and that *for life*.

Would it be asking too much of you to write an editorial in the AMERICAN JOURNAL OF PUBLIC HEALTH on the danger of abusing the ignorance of the public or the credulity of the public, whether by quacks or by sincere public health officers? There is in any case no use in putting weapons into the hands of your supposed enemies.

Sincerely yours,

BENJ. C. GRUENBERG,
Managing Director.

HENRY F. VAUGHAN, D. P. H.

The Health of the School Child—
Sir George Newman, in the *Annual Report of the Chief Medical Officer of the Board of Education* (England) for the year 1926, recognizes two common types of ill-balanced children; (1) the catarrhal child, in whom there is a tendency towards hypertrophy of the lymphoid tissue and a special susceptibility to inflammatory exudation from mucous surfaces and (2) neuropathic child, who shows a lack in nervous regulation of the whole body with atony of the muscles, the weight of the body being balanced by stance rather than by muscular action.

The author recommends that the following queries regulate the status of the abnormal child: (1) Is the debility due to general nurtural neglect in the child's home—insufficient sleep, inadequate and irregular meals, or vitiated atmosphere? (2) Is the debility the manifestation of some particular disease such as tuberculosis, rheumatism, or rickets? (3) Is it the after-effect of recent illness, measles, or broncho-pneumonia? (4) Is it an early sign of some oncoming disease? (5) Is it due primarily not to bodily disease, but to neuropathic or psychopathic disease?

The Problem of Goiter—The London *Lancet* for December 10, 1927, gives an interesting resumé of the International Conference held in Switzerland last August on the problem of goiter. In discussing the etiology and epidemiology of the subject McCarrison still insists that goiter is a syndrome including a great number of conditions of various origin. For endemic goiter—

He finds the pathogenetic explanation in a reasoned combination of iodine deficiency theory and infection theory. The latter is warmly

supported by Galli-Balerio, who is only an adherent of the iodine deficiency theory to the extent that iodine is able to neutralize the noxa causing goiter where the latter is not acting too intensively. Iodine is the antidote whose employment should not prevent an interest being taken in all the essentials of general hygiene.

The Congress almost unanimously refused the specific goitrous infection theory.

The aims of goiter prophylaxis as brought out in the discussion, may be shortly summarized as follows: for man and cattle to supply the necessary physiological ration of iodine; for the already marked school goiter to combat this by individual iodine treatment in medical hands; to ensure a normal composition of food-supply containing vitamins; and finally, to combat the misuse of iodine in unphysiological doses, especially in the adult. Should a more general application of these principles result, the conference will have done something not only for the scientific recognition of endemic goiter, but also for its abolition.

It is interesting to note that at an International Congress on endemic goiter held in Lyons, in 1841, Dr. Prevost of Geneva ascribed goiter to the absence of bromine or iodine in drinking water. Ten years later the French chemist, Chatin confirmed this theory in its essential points. The present discussion of goiter and its prevention, therefore, dates back at least as far as the Conference of 1841.

Bureau of Health, Richmond, Va.
—The 1926 report of the Bureau of Health forms a part of the annual statement of the Department of Public Welfare of Richmond. Two epidemics are noted, one of rabies in dogs, and the other of influenza and pneumonia, the latter being particularly severe among colored persons. Former records for typhoid fever were broken,

with less cases and deaths reported than usual, a death rate per 100,000 of 1.1 being recorded. An effective chart of the typhoid fever experience, 1880-1926, adds interest to the report. Efforts to eliminate dry closets and wells were continued and a reduction in the number of unsewered homes from 642 to 411, with a reduction in the number of wells from 159 to 108, was recorded.

On the basis of an estimated population of 189,084, a crude death rate of 16.05 is recorded; 23.8 for colored and 12.8 for white persons. The birth rate for white persons was 19.24; for colored persons, 25.68; for both combined, 21.13. In all, 21 per cent of the births were attended by midwives. An infant mortality rate of 107 is reported, the rate for colored infants especially being higher than recently. A declining birth rate, the influenza epidemic, an increase in deaths from infantile diarrhea, and increases in deaths from premature birth and congenital debility, are noted as important factors in the infant mortality rate.

The milk supply comes from 10,063 cows on 239 dairy farms in 28 counties within the state. All herds have been tuberculin tested and reacting animals removed. The average score of dairies at the end of the year was 81.0. This entire report has been carefully prepared and contains many interesting statistical tables with descriptive text.

Maternal Mortality—Dr. Samuel J. Crumbine made several pertinent statements on January 3 at Battle Creek while addressing the Third Race Betterment Conference on "Has Maternal Mortality any Significance in Race Deterioration?"

Based upon figures representing the

39 states included in the U. S. Death Registration Area in 1924, it was found that in 33 states, maternal deaths were second in importance only to tuberculosis as a cause of death among women 15 to 44 years of age. In one state, maternal deaths shared second place with heart disease. In 4 states, maternal deaths formed the leading cause of death of women 15 to 44 years of age.

Since the ultimate consequences of maternal deaths are measured in their effect on the lives of surviving children and since an average of two children survive each maternal death, the annual loss of women from maternal causes is doubled if its effect on the future of their children is considered. The maternal death is also a forerunner of a high infant mortality and, likewise, finds expression in its social effect by increasing child delinquency. Maternal deaths are a chief disrupting factor in family life, and the state, which depends for its solidarity on the preservation of the family, must recognize the care of mothers as its chief responsibility.

Diphtheria Prevention—The November issue of *Public Health News* published by the New Jersey State Department of Health discloses the fact that diphtheria was more prevalent in the State of New Jersey during the first 9 months of 1927 than it was during the corresponding period of the preceding year, there being 3748 cases reported for the 1927 period, and 2557 cases for the first 9 months of 1926.

This issue of *Public Health News* contains a very timely and complete description of active immunization against diphtheria, and detailed description of the organization and maintenance of diphtheria prevention clinics.

LABORATORY

C. C. YOUNG

MEDIA FOR MILK COUNTS

JOHN F. NORTON, Ph.D. FELLOW A. P. H. A.

University of Chicago, Chicago, Ill.

THE fifth edition of *Standard Methods of Milk Analysis* (1927) specifies a "standard beef extract agar" for use in the standard plate count for the number of bacteria in milk. These methods also approve the use of dehydrated media. It is fully recognized that the specifications for the beef extract agar medium are not so exacting that two laboratories will prepare exactly the same material from a standpoint of bacterial nutrition. Indeed, it is probable that different batches made in the same laboratory will not be entirely uniform in chemical composition. The particular brand of beef extract or peptone or agar used will determine this composition and the rather lenient pH range will also affect the number of colonies appearing on an agar plate under the specified standard conditions. It must also be remembered that no medium will give the true bacterial count. Nevertheless, it is believed that with careful technic the "standard beef extract agar" is a practical medium for use in laboratory control tests for milk supplies.

However, no standard procedure should be regarded as giving a final answer to any laboratory method. It is perfectly proper to question the validity of such a standard and to attempt to improve upon it. It is fairly safe to predict that changes will sometime be made in the present standard medium. It is also possible that an entirely different medium may be devised that will give better results. The ideal medium for

the counting of viable bacteria in milk is one which is simple and cheap to prepare; will contain ingredients of uniform and known chemical composition so that the composition of the medium at time of use will not be variable; will allow the ready growth and recognition of colonies of bacteria; and will give uniform colony counts. Some of these requirements are interrelated. I have not included a specification that an ideal medium will yield a maximum number of colonies. If uniform results are obtainable, a maximum count would seem to be of minor importance in a control laboratory. If bacterial standards are used they can be set on the basis of the medium employed just as such standards must be devised on the basis of the conditions in the community served.

Since 1915 a number of articles have appeared dealing with the problems above outlined. Berry¹ attempted to modify meat juice-peptone media so as to obtain more favorable growth conditions and at the same time lessen the cost. She found that with the standard medium recommended at that time, dilution of the medium up to about 1-8 actually increased the number of colonies appearing and that a dilution of 1-12 gave about the same count as the original medium. Sherman² showed that more and larger colonies could be obtained when lactose was added to the nutrient agar medium. Sears and Case³ maintained that the standard medium then in vogue was deficient in nutrient material

and advocated the use of sterile milk for dilution blanks to furnish supplementary food. Ayers and Mudge⁴ have suggested a milk powder medium on which are obtained relatively high counts, large colonies and some bacterial type differentiation. Supplee, Whiting and Downs⁵ made a rather extensive study of variations in milk counts as affected by the medium used and by the incubating temperatures. They advocated the use of dextrose agar at 37°C. Parker and Byers,⁶ Supplee and Ashbaugh,⁷ and Zoller⁸ have confirmed the claims of Ayers and Mudge for the milk powder medium. Frobisher⁹ has compared the results obtained with standard agar, lactose agar, milk powder agar, milk powder agar with yeast and milk powder agar with 1 per cent lactose. All of the enriched media gave higher total counts and larger colonies than the standard agar. He appeared to favor lactose agar as the most suitable medium. Norton and Seymour¹⁰ compared the counts on five different media—"standard" meat extract agar, meat infusion agar, dehydrated meat extract agar, dehydrated peptonized milk agar, and Ayers' milk powder agar. They obtained somewhat higher colony counts on the two latter media than on "standard" or meat infusion agar. The dehydrated nutrient agar was intermediate. However, the coefficients of variation indicated that somewhat

more uniform counts were obtained with the "standard" and meat infusion media which in the authors' opinion served to offset the more easily counted plates obtained with media containing milk.

The ideal medium for obtaining the bacterial count of samples of raw or pasteurized milk has not been devised. Valid criticisms have been made of every medium so far suggested. It seems to the writer that we know too little of the fundamental chemical properties of our media. We must study these more intensively than has yet been done. Peptone is a common ingredient of our media. How can we expect to obtain uniform results from a variety of peptones? This situation has been recognized and is being attacked. But if this difficulty is solved still others remain. A more accurate knowledge of the fundamentals of bacterial nutrition is the only final solution.

A SATISFACTORY METHOD OF STAINING BLOOD SLIDES FOR MALARIA

WM. KRAUSS, M.D.,
Memphis, Tenn.

THE slides coming into public health laboratories for examination for malaria parasites are usually rather unsatisfactory and often quite unfit for examination by the ordinary Wright method.

I have encouraged my doctors to make rather thick smears, spreading the blood

with one slide upon the other, "like butter upon bread." Such smears are just distinctly red and correspond to the thicker portion of very bad smears.

The slides are fixed in methyl alcohol containing 1 per cent official hydrochloric acid for 3 to 5 minutes. They are

then rinsed under the tap and further washed in a staining dish in running water for 10 minutes.

They are then stained by immersion in a Coplin jar as follows:

- (a) 1 c.c. Wright stain
2 c.c. Methyl alcohol
Distilled water sufficient to make 50 c.c.

Mix the stain and alcohol and pour into the water. Leave in the stain for 15 minutes and rinse in tap water.

- (b) Giemsa Method:
1.5 to 2 c.c. Giemsa stain
50 c.c. Distilled water

Pour the Giemsa into the water. Stain the slides for 30 minutes.

- (c) Have on hand:
1. 1% aqueous solution Eosin W.g.
2. 1% aqueous solution Azur No. 11 (Gruebler)

To 50 c.c. distilled water add 1 c.c. solution No. 1. Stir well, then add 2 c.c. solution No. 2; stir and pour into the Coplin jar containing the slides. Stain for 15 minutes.

These three formulae permit a choice of the stain to which one is accustomed. The advantage of the last named one is that the stain never "goes bad."

One batch of slides will exhaust either of these staining solutions.

Single slides may be stained face down in a Petri dish, supported on a match, in a quantity of stain sufficient for the purpose.

With some practice one can examine these acid-fixed slides in half the time required for the ordinary method. The proportion of positive finds will be materially higher.

The acid fixation is not so desirable for the regulation thick film of Ross as the original Ross Method modified by Schilling and Barber. However, the film is less likely to peel off. The objection is that the background of coagulated albumin prevents a clear view of the parasites. This objection does not apply to the thinner or intermediate smears.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

Longevity of the Presidents— Although the number of lives studied is entirely too small for positive statistical analysis there seems to be sufficient evidence to conclude that the duties of the presidency have shortened the lives of the presidents since the Civil War. The average age at inauguration of the 29 presidents was 54.31 years, Theodore Roosevelt at 42 being the youngest and William Henry Harrison at 68 the oldest. The average age at death of the 27 presidents who have died is 68.41 years and our one living ex-president, Chief Justice Taft is now 70. The average age at death of the 15 presidents of the pre-Civil War era, from Washington

to Buchanan was 73.8 years whereas that of the 12 deceased presidents of the post-Civil-War period was only 61.7 years.

According to life tables the combined expectation of life of the 15 presidents of the pre-Civil-War period at accession was 229.65 years. They actually lived 250.02 or 20.37 years in excess of the expected. The combined expectation of life on assumption of office of the 12 deceased presidents from Lincoln to Harding was 228.81 years but they lived only 123.12 years or 105.69 years less than their normal expectancy. If the life expectancy of Coolidge and Taft should be fulfilled, the years actually lived by the post-Civil-War presidents would be

164.08 or still 105.69 years below the expected and the average life tenure of the 14 since they assumed office would be 7.55 years below the expected as compared with 1.35 years above the expected for the 15 presidents prior to the Civil War. Of the 15 pre-Civil-War presidents, 9 exceeded their life expectations at accession, but of the 12 deceased presidents since 1861 only Grover Cleveland lived beyond his normal expectancy by 1.3 years. Even if the 3 presidents, Lincoln, Garfield and McKinley, who were assassinated since 1861 had lived out their life expectations the post-Civil-War presidents would still fall far short of living as long as expected at the ages at which they were inaugurated.—*Stat. Bull. Met. Life Ins. Co.* 8:2 (Dec.), 1927.

The Principal Causes of Death in 1926—The Department of Commerce reports a slight increase in the 1926 death rate for the death registration area of the United States, which comprises 89.8 per cent of the estimated population of the country. The death rate in 1926 was 12.2 per 1,000 population as against 11.8 in 1925.

Heart disease continued to increase and the death rate rose from 185.5 in 1925 to 199.1 in 1926. Pneumonia and influenza recorded large increases from 93.5 in 1925 to 102.5 in 1926 and 29.6 in 1925 to 40.7 in 1926 respectively. The death rates in 1925 from nephritis (96.3), cancer (92.6) and tuberculosis (86.6) rose in 1926 to 98.3, 94.9, and 87.1 respectively. Diabetes increased from 16.9 in 1925 to 18.0 in 1926, measles from 2.3 in 1925 to 8.2 in 1926 and whooping cough from 6.7 to 8.9. Deaths from accidental causes increased slightly, from 78.3 to 78.6, while deaths from automobile accidents rose from 17.0 to 17.9 and suicides from 12.1 to 12.8.

The principal decreases in rates were from diarrhea and enteritis under 2 years

which fell from 31.5 to 27.0 and typhoid and paratyphoid fever from 8.0 to 6.5 per 100,000 population.—*Department of Commerce Preliminary Report*. Dec. 30, 1927.

Diphtheria and Scarlet Fever in Rio de Janeiro—A study of 520 Brazilian children and adolescents showed only 0.8 per cent with a past history of diphtheria and 0.6 with a history of scarlet fever. In North American surveys these percentages varied from 7.5 to 15 for diphtheria and from 8 to 27 for scarlet fever. The large number of negative Schick and Dick tests in Rio de Janeiro, however, indicates that sub-clinical infection with diphtheria bacillus and *Streptococcus scarlatinae* must be more common there than in cities of the United States, where the case rate from these diseases is much higher. A clinical case of either of these diseases in that city, therefore, might be regarded as an accident in the immunization process due to particular susceptibility of the individual, an unusually massive infection or temporarily increased pathogenicity of the microorganism.

Brazilian children seem to develop immunity especially to the streptococcus toxin at an earlier age and to a greater extent than do children in New York City. The very high percentage of negative Dick tests among children, particularly in orphanages, strongly suggests an exceptional racial capacity to develop immunity to scarlet fever. This theory is strengthened by the fact that there has not been any appreciable mortality from scarlet fever since 1880.—James A. Doull, Manoel J. Ferreira and Decio Parreiras. *J. Prev. Med.* 1:513-527 (Nov.), 1927.

Common Infectious Diseases in Brazil—The results of this study confirm the observations from other studies that scarlet fever is rare and diphtheria quite infrequent in the tropics. Only 3

of 519 persons between 8 and 20 years of age stated that they had ever had scarlet fever, and 4 of 521 had diphtheria. Of 266 over 20 years, 6 had had diphtheria and 4 of 319 had scarlet fever. All of these having a history of scarlet fever came from the southern and less tropical sections of Brazil. The diphtheria mortality rate in 1920 and 1921 in Rio de Janeiro was 5.3 and in the same two years there were only 6 deaths from scarlet fever. In Sao Paulo, 50 miles south of Rio de Janeiro, and having a cooler climate, the death rate in 1920 was 12.2 for diphtheria and 10.6 for scarlet fever. In 1918 the scarlet fever death rate rose from 5 to 23 but dropped to 0.5 by 1923.

Measles, mumps, whooping cough, and chicken pox, however, seem to be about as common in Brazil as in North America. The mortality from measles in Rio de Janeiro, 1917-1923, averaged 25.5 per 100,000 population, rising to 51.9 in 1925. The whooping cough mortality in Rio de Janeiro in 1917 to 1923 was 22.1. Sao Paulo in the same period had rates averaging 8.3 for whooping cough and 13.7 for measles.—James A. Doull, Manoel J. Ferreira and Decio Parreiras. *J. Prev. Med.* 1:503-512 (Nov.), 1927.

Infantile Paralysis in Haverhill—The infantile paralysis epidemic in Haverhill, Mass., with a case rate of 2.2 per 1,000 population exceeded the previous maximum incidence rate of 1.8 in New York in 1916 and of 1925 in New Zealand and Iceland. At the waning of the epidemic in the last of October, 105 cases with 15 deaths had been reported. About 1 out of every 70 of the 4,000 children of preschool age had the disease and 7 deaths occurred in this group. There were 45 cases and 8 deaths among the 12,000 children of school age. The state report shows that up to the last of October, 908 cases had occurred, so that Haverhill has had about 10 per cent of

the total cases reported for the entire state.

The records of the Board of Health show that in the 17 previous years there have been 172 cases and 29 deaths from the disease in Haverhill. One hundred and thirty-three of these cases occurred in cycle years of 1913-1914, 1916-1917 and 1920-1921. Since 1910, 42 or about 25 per cent of the cases occurred among children in Ward 5, in 1917 this percentage increased to 70 while 60 of the 104 cases of the present year occurred in the same ward. Thirty-nine of the 60 patients in Ward 5 were of French ancestry, and 12 of the 15 deaths in the city occurred in this ward, all of them being of French-Canadian descent, and still another death was also in a family of French ancestry.

The average age of the children with the disease was 5 years and 8 months, approximately the same as the average age of previous epidemics. The deaths by ages were: one 10 months, one 2 years, three 4 years, two 5 years, two 7 years, four 8 years and two 16 years. The illness of these 15 cases before death varied from 3 to 12 days.

There were 25 cases in Ipswich, a town of about 6,050 population 14 miles from Haverhill. This incidence rate of 4 per 1,000 is the highest ever known.—George T. Lennon. *Boston M. & S. J.* 197:916-920 (Nov. 17), 1927.

Public Health in Madras—The population of Madras is about 40 millions and is steadily increasing despite the fact that the death rate in 1926 was 24 and the infant mortality 189 per 1,000. There were 24,407 deaths from cholera, 10,457 from smallpox, 2,143 from plague, 91,758 from dysentery and diarrhea, and 337,945 from fevers. Only about 55 mothers per 1,000 receive skilled attention during labor, and this partly accounts for the large number of deaths, 7,142, from diseases connected with childbirth.—*Pub. Health* 41:37-38. (Nov.), 1927.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

RECENT PROGRESS IN REFUSE COLLECTION AND DISPOSAL*

THERE has been comparatively little noteworthy development in the field of garbage and refuse collection and disposal during the past year. Such projects as are of general interest are briefly summarized herewith.

Birmingham, Ala.—In November, 1926, Birmingham awarded a contract for three incinerators with capacities of 60, 90 and 180 tons per 24 hours. The contract entered into amounted to \$352,800. The plants are being built by C. O. Bartlett and Snow Company and are of the top charged, outside storage, high temperature type, with forced draft.

Los Angeles, Calif.—The construction of an incinerator of 800 tons per 24 hours capacity at a cost of \$370,000 was completed in 1927 for the city of Los Angeles by the Nye Odorless Incinerator Company. The furnaces are of the beehive type connected to a common flue. The capacity is guaranteed when burning 65 per cent by weight of garbage and 35 per cent by weight of rubbish. It is understood that the garbage consists chiefly of market refuse.

* Report of the Committee, presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

Buffalo, N. Y.—A refuse incinerator having a capacity of 500 tons per 24 hours has been almost finished for the City of Buffalo by the Hiler Engineering Company of New York. The furnaces are of the outside storage, top charged, high temperature type.

Indianapolis, Ind.—The garbage reduction plant at Indianapolis has been put into operation during the last month or two. This plant comprises apparatus for reducing the garbage to grease, stock food, tankage, etc. A noteworthy feature is the production of stock food which appears to have a first rate market for feeding hogs and chickens.

A plant of different type but producing also a stock food has been operating during the year at Kansas City.

In closing, it is suggested that those interested should read an article published in *Industrial and Engineering Chemistry* for May, 1927 by Harrison E. Howe of Washington, D. C., entitled, "Progress in Garbage Reduction."

Sewage Disposal in 1927—This is a discussion of sewage disposal, with special reference to English practice. Land irrigation is probably the soundest method of purification where soil and subsoil conditions are suitable, and the volume of sewage to be treated is well within the purifying capacity of the area

available—1 acre per 100 contributing population. Contact beds are not considered a sound economical method of freeing sewage from its tendency to putrefy. Percolating filters are popular and deservedly so. The initial cost is higher than for an activated sludge plant but maintenance and operating

costs are lower. Compared with an activated sludge plant a percolating filter installation may be called "foolproof," and its bacterial population is wonderfully adaptable to varying conditions, including change of temperature and character of sewage to be treated. The activated sludge process is not so popular as it was, probably as a result of "the untoward zeal of some of its advocates and their belated consciousness of its limitations." It has been proved to be scientifically sound and its suitability for certain kinds of work is unchallenged; but it is not suitable for the treatment of all kinds of sewage, nor is it economically adaptable to all situations. Its successful application requires more knowledge and skilful management and it is not, generally speaking, so reliable under all circumstances as the older and better tried methods. Lagooning is the most popular method of sludge disposal. The Imhoff tank has not found favor in England.—J. D. Watson. *Surveyor*, 72:5 (July 1), 1927. Abstr. R. E. Thompson.

Practical Swimming Pool Sanitation Control—Detroit's 37 pools represent all types, from old fill and draw to modernly equipped pools with recirculating pumps, hair strainers, sand filters and sterilization. Only two are outdoor pools.

Inspections are made every 2nd and 3rd day and water samples taken. Bacterial standards are: (1) A median monthly total count of not over 2000 per c.c.; (2) not over 50 per cent of samples in any month shall show presence of *B. coli*; (3) not over 20 per cent of samples in a given month shall show a colon count of over 10 per 100 c.c.

The publication of the standing of the pools has been an incentive to meet the requirements.

It does not require modern equipment to stand well upon the list as to sanitation. The personnel has much to do with results obtained. Good coöperation is

obtained from those in charge of the swimming pools.—W. H. Cary, Jr. *Nation's Health*, 9:16 (May 15), 1927. Abstr. L. M. Fisher.

Some Recent Experiments in Fly Control—The experience of the U. S. Bureau of Dairying in controlling flies on an experimental farm at Beltsville, Md., during the year 1924 and 1925, is given in detail. House flies which prefer horse manure as a breeding place but breed readily in cow manure, and stable flies which prefer damp straw or hay on which to lay eggs but will readily lay eggs upon straw mixed with manure, had always been numerous.

In order to control breeding, all manure was hauled away at least once each week and box stalls in which considerable straw was used, were cleaned and the floors scraped regularly. The manure was either spread on fields or placed in large piles one-half mile from the buildings. Failure to remove manure on time resulted in a marked increase in flies. The author holds that the elimination of breeding places is the greatest factor in fly control.

Fly traps were also used in this work due to inability to eliminate all breeding places on the property and to the presence of breeding places on neighboring farms. In discussion it was brought out that experiments in liberating marked flies by the U. S. Department of Agriculture at Dallas, Tex., showed that the house fly traveled 11 miles in 4 to 7 days, and some were caught as much as 17 miles from the point of liberation. The length of flight indicates the necessity for using traps in addition to controlling local breeding places. Ten cylindrical fly traps similar to those described in the U. S. Department of Agriculture *Farmer's Bulletin No. 734* were used in scattered positions. They were baited with blackstrap molasses from sugar cane, diluted with 3 or 4 parts of water which, when it fermented, drew

flies in large numbers. Bait was replenished about once a week. The effect of the traps could be noticed after about 10 days use during August when flies were numerous. During 1925 the 10 traps caught 86 gallons of flies estimated by making counts to run 50,000 or 60,000 flies to the gallon.

As an added protection against flies entering the milk room, a 30-inch electric fan was attached to the porch ceiling causing a slight air current against the screen door which proved very effective in keeping flies off the screen door and porch.

To protect cattle from horn and stable flies, a spray made by soaking one pound of partially opened dried pyrethrum flowers (purchased in 20 lb. lots) in two gallons of kerosene oil for 48 hours was used. This is a killing spray rather than a repellent. It cost from 35 to 40 cents per gallon. It was applied by air pressure sprayer using a nozzle capable of producing a very fine vapor. Horn flies were quickly killed if caught in a cloud of vapor as they swarmed after the first spray struck them. While horn flies lay their eggs in fresh droppings their number was appreciably reduced after a week of daily spraying. Stable flies were killed by spraying them as they were found sucking blood on the cows' legs. Stable flies were much harder to control, however.

Care should be exercised not to wet the cattle unnecessarily with the spray as the kerosene is irritating. When this spray was used one hour before milking no difficulties were experienced in causing odors or tastes in the milk.

Results of this fly control work are reported as satisfactory. No statement is given as to the total cost of control. There was considerable discussion of this paper.—R. J. Posson. *Proceedings of the 19-20th Conference of Amer. Assn. of Medical Milk Commissions and Certified Milk Producers Assn. of America*. pp. 322-327. Abstr. W. D. Tiedeman.

Distribution of Cellulose in Imhoff Tanks—This is a preliminary report on the cellulose content and distribution in fresh sewage solids of an Imhoff tank at Plainfield, N. J. The solids were collected by suspending pails for 24 hours in the flowing through compartment at the inlet, middle portion and outlet. Samples from each point and from the mixture of the three portions were analyzed. A table is given showing results of solids concentration, volatile matter and cellulose content. A selective settling is indicated and, in view of the relation of cellulose to CO₂ production, the efficiency of the tank would be greatly affected by the design and the opportunity for reversal of flow.—H. Heukelekian. *Pub. Works*, 58:133 (Apr.), 1927. Abstr. A. S. Bedell.

Great Advances in Water Softening—This article contains an excellent summary of modern ideas and present methods of water softening. It emphasizes advantages and disadvantages and describes such equipment as pneumatic conveyors for the handling of chemicals, continuous lime slaking machines, mechanical agitators for chemical mixing, sludge removal equipment and recarbonization plants. Tentative estimates are also given to compare the cost of zeolite and soda-ash treatment as applied to the Columbus filtration plant. Natural gas and kerosene oil are recommended as the most suitable fuels to be used for the generation of carbon dioxide gas. For large installations producer gas made from coke and then burned to complete combustion is the most economical method. The paper contains the description of such a plant now under construction at Columbus, O. The effects of recarbonization and of the addition of sodium aluminate upon the corrosive properties of a water are also discussed.—Charles P. Hoover. *Water Works Eng.*, 80:991 1019 (July 6), 1927. Abstr. W. L. Havens.

Résumé of Progress in Chlorination—The early history of chlorination is reviewed briefly, and recent developments are discussed in some detail, with special reference to Toronto, Ont. The employment of prechlorination is extending. In Toronto, the cost of operation of the drifting sand plant has been reduced by \$150,000 over a period of 4 years by applying chlorine to the raw water instead of alum at such times as the water is physically good. With moderately turbid water, considerable economy can be effected by applying small doses of chlorine and reducing the alum to just sufficient for clarification. The observation that chlorination aids coagulation has been confirmed at Toronto. Other advantages of prechlorination are reduction of filter load in heavily polluted water and increased rates of filtration; and it constitutes an additional safeguard in the treatment of water subject to rapid changes in quality. Chlorine is being increasingly employed for destruction and prevention of algal growths in filter underdrains and sedimentation basins. Applications of excess chlorine and, subsequently, copper sulfate, were ineffective for reducing the loss of head which rapidly increases in slow sand filters at Toronto during a 2-months period each spring. The recently inaugurated super-and de-chlorination treatment for prevention of taste at Toronto is outlined and discussed.—Norman J. Howard. *Canad. Eng.*, 52:116 (Mar. 8), 1927. Abstr. R. E. Thompson.

A Study of Refuse Collection and Disposal in Sydney, Australia—The article is an abstract of Mr. Newman's comprehensive report on the subject. The refuse burnt in the destructors in Sydney is of three types, household refuse, early morning refuse and trade refuse. Household refuse represents 60 per cent of the total and consists of garbage, dirt, ashes, tins and paper, weighing 750-800 lbs. per cu. yd. "Early

morning refuse" is coined to describe the refuse collected between 6:30 and 8:30 a. m., intermediate in composition between household and trade refuse, consisting of shop, office, cafe and hotel refuse, averaging 36 per cent paper and weighing 500 lbs. per cu. yd. Refuse from municipal fish, fruit and vegetable markets is converted by a private company into fertilizer.

Owing to mixed collection, the results of analyses of Sydney refuse differ from those prevailing in America, being 44.7 per cent water, 29.7 per cent combustible, and 25.6 per cent ash, and having a calorific value of 3,007 B. T. U. The recommended method of disposal is separation-incineration, and the specifications for a new destructor should provide that it burn, without additional fuel, mixed refuse containing not over 900 lbs. of water per ton and not less than 800 lbs. of combustibles.—R. K. Newman. *Am. City*, 37:61 (July), 1927. Abstr. A. S. Bedell.

Abbreviated Report of the Government (Holland) Water Supply Bureau for 1925—A short account is given of the rural supply projects inaugurated and in course of inauguration under the bureau's auspices, outlining the many and various difficulties with which such undertakings have to contend. The manifold functions of the bureau include, for example, technical advice on such matters as deferrization and demanganization. The government is keenly alive to the desirability of providing reliable water for the rural population as well as for the urban. In more prosperous times it even participated financially in certain approved projects and even now is prepared to assume in some cases a certain contingent liability. Upon the bureau rests the responsibility of seeing that these rural supply projects are established upon the soundest possible basis, both technically and financially. Activities to this end are summarized un-

der 93 headings. Perhaps the greatest difficulty to be surmounted is that of popularizing the idea of paying for water among the thrifty and independent Dutch. Some of the propaganda work is described. In an appendix, Engineer Markus of the bureau lists for 94 Dutch waters the hardness as deduced by the application of certain formulae from the electrical conductivity and the hardness as found by analysis. Agreement is moderately satisfactory.—*Verslagen En Mededeelingen Betreffende De Volksgezondheid*, 7:649 (July), 1926. Abstr. Frank Hannan.

Sewage Plant Records—This is a discussion of the purpose of the plant records and explanations of kinds of data worthy of recording. Purpose fourfold to show: plant efficiency plant effectiveness, line of defense against unjust criticism, adequate information for plant improvement. Data needed include: number and kind of connections, continuous meter records of flow at outfalls, oxygen demand by methylene blue test, suspended solids, and pH determinations at various points of treatments. Determination of ammonias yields little information of value. Illustration is given of value of records in showing need of plant enlargement where metering had cut down per capita water consumption 20 per cent and population had increased 40 per cent. A method is given in detail for converting from plant data giving "suspended solids retained" to amount of sludge to be moved.—John R. Downes. *Water Works* 66:335 (Aug.), 1927. Abstr. W. R. Schreiner.

Some Problems of Seaside Health Resorts—The author discusses in a somewhat pessimistic but none the less candid manner the numerous problems confronting the governing authorities of a seaside resort.

Sewage and refuse disposal, particularly present difficulties not encountered at

inland or all-year-round communities. In order to be successful in so far as attraction and popularity are concerned, the psychological aspect of the summer visitor must be considered. In the matter of the sewer line extension and outfall, and the avoidance of any hint of even storm water deposits near the beaches, as well as too frequent refuse collection in order to cater to the esthetic rather than the practical, considerable unnecessary expense is involved.

The widely varying conditions of the summer season and the "off-season" cause problems of housing and unemployment seldom encountered elsewhere.

Other features discussed, but not directly concerning the public health, are local attractions, development of sea front, the economics of bathing pool operation and bathing privileges, tennis courts and golf courses, storm shelters and comfort stations and finally the highway and motor car problem.—Leslie Roseveare. *Surveyor* 71:625 (June 24), 1927. Abstr. H. N. Old.

Camels and Plague—The method of transmission of plague from the Orient along caravan routes to Europe has long been unexplained. In connection with a study of 4 plague cases in Astrakhan, obviously caused by ingesting salt meat from a dead camel, the camel was suspected as being part of the chain of transmission.

Plague cultures inoculated into 4 camels produced typical plague. It was also produced by feeding the animals green plants dipped in plague cultures. Infected camels might easily contaminate the fodder to be eaten by others and in that way spread the line of infected animals over long distances. At the European end of the line, and since the ingestion of the flesh of dead animals may produce disease, the way rodents might be infected can readily be seen. *Centralbl. f. Bakteriöl.*, 98:24, 1926; *Nation's Health* 9:58 (Apr. 15), 1927.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D. AND LEONARD GREENBURG, PH.D.

Experimental Studies On the Effect of Ethyl Gasoline and Its Combustion Products—This bulletin of 447 pages including 105 pages of appendix is replete with tables, graphs, and illustrations to complete the text of the extensive studies made at the Pittsburgh Experiment Station of the U. S. Bureau of Mines extending from December 6, 1923, to August, 1925. Part I concerns the physiological effect of exhaust gases from engines using ethyl gasoline. Part II, the effects of inhalation of unburned vapors from ethyl gasoline and other motor fuels (gasoline-benzol mixtures, straight benzol vapors and various combinations of ethyl gasoline with these). Part III, deals with skin absorption experiments with ethyl gasoline, 50-50 benzol-gasoline blend, benzol, and benzene (c.p.). In this part are also considered inhalation experiments with animals treated with ethyl gasoline and with other mixtures and chemicals above stated. The following are abstracted from the general summary and findings of investigations which appear on pages 14-28:

Part I. Physiological Effects of Exhaust Gases from Engines Using Ethyl Gasoline

Campaign 1. Tests Conducted with Gasoline Containing the Commercial Amount of Ethyl Fluid

1. Duration of exposure—December 6, 1923, to July 26, 1924.

7. Storage of lead by animals—No distinct storage of lead was found in the animals exposed during Campaign 1. With only two exceptions the results of analysis were similar to those obtained from control animals. The exceptions were a 6-hour exposure rab-

bit and a 6-hour exposure guinea pig in which the lead found was 0.190 and 0.094 mg. per 100 g. of body weight, respectively.

8. Pathology—No distinct pathological lesions attributable to lead poisoning were found.

9. Hematology—No anemia, change in red- or white-cell counts was noted, nor was there any increase in polychromatophilia or punctate basophilia, other than that found in control animals of like species.

10. Symptoms—From the observations made it appears that the exposure to lead during Campaign 1 was not productive of the characteristic symptoms of lead poisoning. The only symptoms exhibited were those of intercurrent disease and were impartially distributed among control, 3-hour, and 6-hour exposure groups, and without dependence on the total period of exposure. With the above exception the animals were healthy, lively, and had good appetites.

12. Manifestation of effects—The effects of exposure to the concentrations of lead prevailing in the air during this campaign were not manifested by the storage of lead, pathology, hematology, symptoms, weight and growth of the animals exposed.

Campaign 2—Tests Conducted with Gasoline Containing Five Times the Commercial Concentration of Lead Tetraethyl

20. Concentration—It appears that the conditions under which the animals were exposed is close to the threshold concentration for monkeys, dogs, rabbits, and guinea pigs. Some animals of each group showed little or

no storage, while others showed distinct storage though not a comparatively large amount.

27. Tests on men—Tests conducted on men breathing exhaust gases from ethyl gasoline show that on the average, 87 per cent of the inhaled lead dust was again exhaled, leaving only approximately 13 per cent as retained in the lungs and respiratory passages.

Part II.—Effects of Inhaled Ethyl Gasoline Vapor

5. Effect of gasoline on animals—(a) Storage of lead—A number of the animals were examined for storage of lead, and the amounts found were similar to those for unexposed control animals.

(b) Pathology—The general findings in all concentrations were hyperemia of the lungs, granular degeneration of the liver, and granular degeneration of the kidneys which sometimes lead to pitting and scarring, especially in rabbits. . . .

(c) Hematology—The blood changes were minor and of little significance.

(d) Symptoms—The symptoms were unsteadiness, drowsiness, and moderate watering of nose and eyes due to irritation. These symptoms were not noticeable in the lowest concentration (0.10 per cent vapor) and were marked in the 10 per cent concentration. They disappeared shortly after each exposure.

6. Effects of Ethyl Gasoline and gasoline containing higher concentrations of lead tetraethyl and ethylene dibromide—(a) Storage of lead—Some of the animals exposed to 0.10 per cent ethyl gasoline vapor showed distinct storage of lead. Nearly all guinea pigs exposed to higher concentrations showed storage. Nearly all the monkeys, dogs and rabbits which were exposed to 0.3 per cent ethyl gasoline vapor showed storage of lead.

7. Effects of a mixture of equal parts gasoline and motor benzol—(a) Path-

ology—The general findings were acute degeneration of the liver and kidneys, anemia of the spleen, congested adrenals and hyperemia of the lungs. An edema of the lungs was found in animals that died after exposure to 1.0 per cent vapors. These findings are similar to those for gasoline alone.

(b) Hematology—No effect on the number of white cells or hemoglobin content was noted. The red cells showed a tendency toward polycythemia.

8. Effect of motor benzol on guinea pigs—(a) Pathology—The general findings were degeneration of liver and kidneys, anemic spleen, congested pancreas and adrenals, congestion of lungs and an edema in animals dying from exposure to 0.3 and 1.0 per cent vapors. These observations are similar to those for gasoline vapor.

(b) Hematology—No leukopenia or anemia were observed. There was a slight increase in the red cells, also a moderate polychromatophilia.

Part III.—Effects of Ethyl Gasoline When Absorbed Through the Skin

1. Materials used—(a) Water; (b) gasoline; (c) ethyl gasoline (1:1300); (d) gasoline containing 10 times the commercial concentration of lead tetraethyl (1:127) and ethylene dibromide; (e) benzol-gasoline blend; (f) motor benzol; and (g) benzene (c.p.) (C_6H_6).

5. Relative effects of absorption—Greater injurious effects were produced on animals when the material applied could gain entrance to the body through the skin, gastrointestinal and respiratory system than by the skin and gastrointestinal tract or through the skin.

When the material applied could gain entrance to the body through skin and gastrointestinal tract, it was slightly more injurious than when limited to skin absorption.

When the material was applied on rats, guinea pigs, and rabbits so that it could be absorbed through the skin, inhaled and ingested, and if the animals were intimately associated the general effect was more or less independent of the size of the dose administered.

10. Animals treated with benzol—(a) Benzol applied in doses of 0.5 c.c. so that it could be absorbed through the skin, inhaled, and ingested, eventually was found to be fatal for rats and 1.0 c.c. for guinea pigs, but rabbits appeared to be able to withstand doses of 1.0 c.c. if they were not complicated by infections. Guinea pigs that received doses of 1.0 c.c. of benzol in such a manner so that it could only be absorbed through the skin apparently were not injured in health.

(b) The general pathological changes found in the animals treated with benzol were an acute parenchymatous degeneration of the liver and kidneys.

(c) The blood picture was that of a slight anemia, which was manifested by an attempt of an increased production of erythrocytes.

(d) The symptoms of the animals treated with benzol were a local skin irritation which healed and became inflamed periodically. The treatments became more irritating as the tests progressed, and produced convulsions in the guinea pigs that received 1.0 c.c. when they had been on test for some time.

(e) All of the animals treated with benzol lost weight during the first few weeks, but this was regained by those that survived this period.—Sayers, Fieldner, Yant and Thomas, *Report of the U. S. Bur. of Mines*, 1927, Washington, D. C.

Health Aspects of the Wood Working Industries—The following paragraphs are abstracted from the summary of this report:

2. In order to determine the prevalence of nasal irritation, asthma, and dermatitis in this group of workers, clinical examinations have been made of 208 persons employed in thirteen Melbourne joinery and furniture factories, and ten other wood-working employes have also been examined in respect to their dermatological condition.

3. It was found that 78 employes, or 37 per cent, of all factory examinees, presented departures from normal as regards their nasal condition. Of these 27, or 13 per cent, had abnormalities of the nose and throat, which were antecedent to occupation in the wood-working industry. . . . It has also been shown that employes in the age group under 21 were least affected, and that no person engaged less than two years in the wood industry evidenced nasal trouble. . . .

Wood machinists were found to show the greatest percentage affected in all the occupational groups, no fewer than 40 per cent having nasal trouble due to dust inhalation. . . .

4. In 113 persons, an aural examination was made, and abnormalities were recorded in 38, or 34 per cent, of the examinees. . . .

7. Only 1 person, of the 208 examinees, or 0.5 per cent, was found to be suffering from a dermatitis definitely due to a wood-working occupation. In this case, blackwood was the responsible agent. From other sources, 10 further cases were found, one of urticaria, probably occupational, and 9 of dermatitis. . . .

Recommendations—

1. In view of the large percentage of wood-workers found affected with nasal trouble definitely due to the inhalation of wood dust, it is strongly urged that these workers be adequately protected by the installation of an effective exhaust on each wood-working machine, so that the quantity of

wood dust liberated into the air of the workroom be minimized as far as possible.

2. Susceptible persons suffering from a dermatitis due to working with blackwood or other timbers cannot reasonably expect to be cured without cessation of this work, and removal from exposure to the cause of their dermatitis. It is recommended that this question be taken into serious consideration with the object of providing in some effective way for the small number of persons with this peculiar susceptibility.—D. G. Robertson, *Health*, Commonwealth of Australia, V, 5:150-151 (Sept.), 1927.

Health Survey of the Printing Trades, 1922 to 1925—The present survey concerns itself with approximately 300,000 workers engaged in the printing trades during the years 1922-1925. The information was obtained by means of a questionnaire sent to printing plants throughout the United States and Canada. The number of replies received was 2,000, representing 47 states, District of Columbia and certain portions of Canada. The survey revealed the fact that general conditions were found decidedly more satisfactory than had been anticipated. The sickness rate was apparently rather low. Sanitary conditions, evaluated by means of inspections, were found to be for the most part fairly satisfactory with the exception of an insufficiency of floor space and air space in many establishments. These deficiencies were found to be chiefly inherent in old printing plants. The study also revealed the very interesting fact that tuberculosis is no longer a menace of serious proportions in the printing industry, and lead poisoning likewise was found to be much lower than had been anticipated. The physical and medical examination of printing employes revealed the fact that the men were of good normal physique, their measure-

ments corresponding with those of the soldiers discharged at the close of the World War. There appeared to be a rather high incidence of visual defects, and according to Dr. Hoffman these are the result of ill adjusted posture. He says, "printers who are above the average in stature, unless properly provided with suitable seating facilities, may develop spinal curvature, which is fairly common and closely correlated to eye strain and other visual defects."

Dr. Hoffman concludes, "the problem of lead poisoning in the printing industry while always a grave and potential danger is now, at least in fatal form, of minor importance." For the year 1925 the U. S. Bureau of the Census reports only 5 deaths from chronic lead poisoning among some 300,000 printers. He further analyses the question of tuberculosis, and concludes that the decline in tuberculosis among printers employed in printing trades conforms to the observed decline in the population at large. And lastly, he points out that there exists a higher proportion of deaths from cancer among printers at the present time than existed in the past, the proportion of deaths being 4.2 per cent during the years 1912-1918 and 8.2 per cent during the years 1919-1923.

For all of those persons who are interested in the problem of industrial lead poisoning this study provides a large body of very valuable material.—Frederick L. Hoffman, *Bull. No. 427*, U. S. Bureau of Labor Statistics, Washington, Mar., 1927. L. G.

Annual Report of the Surgeon General of the Public Health Service of the United States for the Fiscal Year 1927—The activities of the Office of Industrial Hygiene and Sanitation of the U. S. Public Health Service for the year 1927 are described in some detail in the present report of the Surgeon General. This office, under the direction of Surgeon L. R. Thompson, has conducted

investigations of tetraethyl lead, occupational health hazards, occupational diseases and industrial absenteeism. Cooperation with certain other government departments and with industrial and other agencies has been carried on by this office also. The most noteworthy of the contributions of the Public Health Service along these lines have been the studies on tetraethyl lead which were continued during the past year. Air samples were obtained in the streets of 14 large cities of the United States as well as in certain garages and other industrial establishments. In addition to these, samples of dust were obtained in a similar group of establishments.

The valuable dust studies of the Service have been continued and 4 of the 7 studies have been completed; namely, the cement, granite, hard coal mining, and polishing and buffing of silverware. During the past year the reports on the cement and granite studies have received their final touches and are now in press. These dust studies will undoubtedly prove to be the most detailed and valuable ones made in the United States. It would appear that every aspect of the problem of dust inhalation has received careful and detailed consideration in these studies.

The Office of Industrial Hygiene of the U. S. Public Health Service has been interested in the problem of illumination for some time, and during the past year, in order to study the problem of distribution to daylight within factories and schoolrooms, an experimental illumination cabinet in the form of a building 30 feet square and about 16 feet high has been constructed in Arlington County, Va. Window space, ceiling height and

floor area may be altered at will, and it is proposed by means of illumination readings continued throughout the year to obtain fundamental data on the distribution of natural illumination in buildings.

The Service is becoming more interested in the problem of smoke pollution of the atmosphere and the loss of light due to smoke, and in order to study this latter problem daylight illumination recorders were installed, one on the lower end of Manhattan Island where the air is heavily polluted and one on one of the buildings on Hoffman Island where the air is comparatively free from dust and smoke. So far but 2 months' records are available but these show a large absorption of light by the atmospheric pollution depending upon the time of day and sky conditions.

The Service has published a very valuable paper on the problem of posture, and an exceedingly valuable bibliography on the literature on this subject has been published in *Public Health Reports*.

Studies on occupational dermatoses, pneumonia among steel workers, industrial absenteeism, illumination in post offices, and coöperation with the Bureau of Standards and the Bureau of Mines have been continued throughout the year. For more detailed information concerning the results of many of these studies the reader is referred to the present report and various papers which have been issued during the past year either in the reports of the U. S. Public Health Service or as bulletins of this office.—Government Printing Office, Washington, 1927. L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Studies On the Effects of Abundant Cereal Intake—Cereals ordinarily used in the household and supplements readily obtainable at the grocery store were fed in combination to experimental albino rats in order to determine the efficacy of cereal supplements other than milk or milk products. The cereals represented were oats, wheat and corn—three different diets in which the cereal was present in amounts of 65 per cent, 80 per cent and 93 per cent respectively. Oatmeal, whole wheat and yellow corn meal represented the cereals. The supplements were whole egg (substituted by egg yolk in the 93 per cent diet), molasses and fresh lettuce. Oatmeal and whole wheat diets furnished the best growth in the 65 per cent series, with yellow corn meal almost as satisfactory, the growth in all cases being better than the conventional "normal." In the 80 per cent series the growth was good to excellent, limited somewhat by the protein content of the ration, the corn meal being again not so satisfactory as oatmeal or whole wheat. In the 93 per cent diet in all cases the growth was barely equal to normal; in the case of yellow corn meal it was below, probably due to low concentration of protein. No signs of rickets were observed, nor any evidence of faulty dentition or vitamin deficiency. In breeding fifteen females on the 80 per cent cereal ration, one only failed to have a litter. The growth rate of the young of these females indicates that the rations satisfactory for growth after the weaning period, are not entirely sufficient for the period of lactation, many of the young being markedly underweight at the time of weaning. The authors conclude that while the 65 per cent series

indicates satisfactory growth, reproduction and lactation, with supplements other than milk, and that growth may be maintained with the 80 per cent level of cereal intake, the experiments are not sufficiently extended in view of the number of substitutes available to determine any general opinion. In all the experiments the cereal rations were cooked before feeding. Comment is made that the ability of man to maintain growth on a large cereal diet is indicated by the Chinese, in whose diet, according to Wu, cereal constitutes 66 to 72 per cent of the calory intake. According to the same authority, this diet is considered adequate except with respect to calcium and milk is as a rule not available as a supplement to the cereal.—George R. Cowgill, Margaret H. Jones, Robert A. Frisch, and G. P. Jackson, *J. A. M. A.* 89:1930 (Dec. 3), 1927.

Study of Tubercle Bacilli in Milk—Meanwell feels that results obtained with artificial cultures of the tubercle bacillus ought not to be accepted as criteria of those which would be obtained with naturally infected milk. Therefore, all his studies were made on milk proved to contain tubercle bacilli by animal experimentation. A temperature of 62.8°C. (145°F.) for thirty minutes does not invariably kill the tubercle bacillus in naturally infected milk, although in most cases this temperature is effective. At a temperature of 60°C. (140°F.) for twenty minutes, tubercle bacilli are in many cases destroyed, but this combination of time and temperature leaves no margin of safety.—L. J. Meanwell, *J. Hyg.*, 26:392 (Oct.), 1927. Abstr., *J. A. M. A.* 89:2072 (Dec. 10), 1927.

Rats and Mice As Disseminators of Typhoid B Bacilli—Organisms of the typhoid B group were found by Friesleben in the feces of large numbers of healthy slaughterhouse animals, but agglutination tests indicated that the types present were not pathogenic to man. Paratyphoid B organisms isolated from the feces of 52 per cent of fifty wild mice and 19 per cent of 100 wild rats, on the contrary, were indistinguishable culturally or serologically from the types pathogenic to man.—M. Friesleben, *Deutsche med. Wchnschr.*, 53:1589 (Sept. 16), 1927. Abstr., *J. A. M. A.* 89:2075 (Dec. 10), 1927.

On the Nutritive Value of Bread—Previous workers have demonstrated the meager vitamin B content of the ordinary white flour with the obvious corollary that white bread is an unsatisfactory article of diet if it constitutes a large portion of the intake as it does in so many families of limited means. Experiments have been recorded by Hartwell presumably confirming the contentions made by others that white bread is satisfactory owing to the vitamin B content of the yeast. The work herein recorded was undertaken to demonstrate the accuracy of statements with respect to the adequacy of white bread and to determine the relative vitamin B content of different portions of the wheat as a result of milling. Experiments were conducted on rats weighing from 70 to 100 g., whose weight and temperature were taken exactly at the same time each week and were kept on a basal ration completely free from vitamin B. In the opinion of these investigators the lowering of the body temperature is a more sensitive indicator of vitamin B deficiency than the weight record, provided the animals are kept in a room at a fairly even and warm temperature. It was found that of all of the products of wheat the germ is richest in vitamin B, equaling, if not excelling, yeast in that re-

spect. Rating the germ as 100 in vitamin B content, then the other products range as follows: middlings 50, bran 33, white flour 0, and yeast 100. It was found impossible to furnish vitamin B sufficient to maintain growth in rats when white flour was used as its sole source. White bread would have to be fed in the proportion of 250-500 per cent of the basal ration, whereas whole meal bread would be satisfactory in amounts from 30-60 per cent of the basal ration and a wheat flour germ bread if constituting 20-40 per cent of the basal ration. It is concluded that the so-called brown breads consisting of considerable bran are not entirely dependable as a source of vitamin B since the so-called "brownness" of the bread is not always proportional to the vitamin B content. It is further argued that the dietary effect of a bread made from a mixture of a patent white flour and the germ is more easily assimilated and furnishes a more adequate supply of vitamin B than the breads made from white flour with a liberal addition of bran. It is suggested that the vitamin B content furnishes a more definite stimulus to peristalsis than does the indigestible bran.—W. Cramer and J. C. Mottram, *Lancet*, 21:1090 (Nov. 19), 1927.

Incidence of Carriers of *B. Aertrycke* (*B. Pestis Caviae*) and *B. Enteritidis* in Wild Rats of San Francisco—Attention is called to the incidence of carriers of food poisoning types of bacteria in wild rats as part of a study of certain factors which may possibly be responsible for food infections and food poisoning outbreaks. In an effort to establish the existence and the incidence of rat typhoid in the rodent population of San Francisco, bacteriological examinations of 775 rats were conducted which revealed 58 rodents infected either with *B. enteritidis* (28 cases) or *B. aertrycke* (30 cases.) At least 2 per cent of the rodents were capable of

shedding highly virulent bacilli. As no rat virus baits had been distributed in the districts from which these animals came it was concluded that the rats were suffering from natural infection. The carrier rate was found to be fairly uniform throughout the city and was 6 per cent in the vicinity of food handling establishments. It is further stated by the authors that it is likely that as San Francisco has a vigilant rat extermination service the conditions encountered there should not be considered as representative of the prevalence of rat typhoid in other large communities.—K. F. Meyer and K. Matsumura, *J. Infect. Dis.* 41:395 (Nov.), 1927.

Effect of *Cl. Sporogenes* On Toxin Production by *Cl. Botulinum*—Conflicting statements by various investigators regarding the effect of other organisms on the growth and toxin production of *Cl. botulinum* led to the experiments reported here which were conducted to ascertain the effect of *Cl. sporogenes* on *Cl. botulinum*, grown in vegetable as well as in meat medium. Asparagus, spinach and meat media were used. In every meat tube *Cl. botulinum* liberated sufficient toxin to kill a guinea pig irrespective of the number of *Cl. sporogenes* spores present. The inoculation of an equal or greater number of *Cl. botulinum* with *Cl. sporogenes* in spinach medium produced toxin with but one exception, when only a hundred spores of each were used. In a few cases the introduction of an overwhelming number of *Cl. sporogenes* spores did not prevent the development of toxin. The deleterious influence of *Cl. sporogenes* is most marked in the asparagus medium. In all three mediums the toxin strength is gradually diminished by increasing the number of *Cl. sporogenes*. The metabolic products of *Cl. sporogenes* are probably not injurious to botulinum toxin since the supernatant fluid of a culture of the non-toxic anaerobe, when added to botulinum

toxin, did not destroy it. Planted together it is not unlikely that *Cl. sporogenes* and *Cl. botulinum* contend for the same food substance, some of which may be necessary for toxin production, and if *Cl. botulinum* fails in securing it little, if any, toxin is formed. The spore suspensions of *Cl. botulinum* and *Cl. sporogenes* inoculated in varying relative amounts into meat, spinach and asparagus mediums, were incubated for 10 days before testing for the presence of toxin.—E. Wagner Sommer and Kathryn Glunz, *J. Infect. Dis.* 41:442 (Dec.), 1927.

Bacteria Concerned in the Spoilage of Haddock—In studying spoilage of Atlantic Coast haddock, the author, found that the predominating organisms isolated from the slime and muscle of the fish were Gram-positive rods constituting a single individual species in the *subtilis-mesentericus* group which is capable of existing in at least two distinctly different modifications. The hypothesis was advanced that the two forms are an example in the *subtilis-mesentericus* group of the rough-and-smooth (R and S) type of bacterial variation observed by numerous investigators of other groups of bacteria. Cultural studies were made of 38 strains of the fish organism grown from single-cells, special attention being given to the differentiation of S and R forms. The strains producing smooth colonies (S type) were asporogenous while the rough or "inactive" strains (R type) produced spores, both types breeding true through several successive transfers in broth and agar alternately at 24-hour intervals. It was possible to convert the R type to the S type and vice versa. The "active" form (S type) which was isolated repeatedly from stale fish muscle was assigned a share in the mechanism of spoilage. The organism studied is designated by the author as *B. "mesentericus-vulgatus"*.—A. H. Gee—*J. Infect. Dis.*, 41:355, (Nov.), 1927.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

Maternal Mortality in the United States—Twenty nations offer data in regard to maternal mortality rates. Among these the United States ranks 19th, Chile being the only civilized nation that shows a higher death rate from accidents and diseases incident to child-birth. Our rate runs one-third higher than that of England, and Wales and more than twice as high as Denmark, Italy, Japan, Netherlands, New Zealand, and Sweden. Even with allowance for statistical error and varying methods of computing rates, women in the United States are not assured of the safety they have a right to demand and which we should be able to give. There has been no improvement in the last 10 years, the rate being 6.1 per 1000 live births in 1915 and 6.4 in 1925, an increase in fact.

Because of this state of affairs this study was undertaken, the proportionate causes of maternal deaths being first summarized. In the death registration area of the United States during 1921 over 40 per cent of all maternal deaths were due to puerperal septicemia. As this is regarded as a preventable cause this 40 per cent can be wiped out; 27 per cent were due to "puerperal albuminuria and convulsions," which condition is felt by all to be at least partly preventable; 10 per cent were due to instrumental and surgical delivery including Cesarean section; the remaining 23 per cent were due to the so-called accidents of pregnancy which included abortion, ectopic pregnancy, puerperal hemorrhage, embolus, puerperal phlegmasia dolens and "certain ill-defined causes." Dr. Baker studied the midwife question to some extent, and while she did not consider the survey complete,

found that the comparative data collected from the various states did not show that the midwife could be held responsible "as a dominant factor in the present high mortality rate", moreover a lessening in the number of births represented by midwives is reported by 22 states.

Hospitalization would seem to be one of the ways in which puerperal septicemia could be decreased but we still fall far short of an adequate number of beds for maternity patients as for all others. Enforced reporting of puerperal septicemia, better obstetrical training in all medical schools, and more facilities for prenatal care, are all considered. Sixteen states have laws making puerperal septicemia reportable but public health authorities have done little with it so far.

Even the best prenatal care will never take the place of skilled obstetrics as Dr. Baker points out, but it has a marked influence in reducing maternal mortality in all city groups where it has been tried out, the rate being cut down from one-half to two-thirds of the figure for the city as a whole.—Josephine Baker, M. D., Dr. P. H., *J. A. M. A.*, Dec. 10, 1927.

Mothers and Babies in New Zealand—New Zealand's *Annual Report* for the year ending March, 1927, states that she still carries the lowest general death rate (not given) and the lowest infant death rate—39.76. The infant death rate has declined slightly in the past year. This decline came in the neonatal period and slight as it gives us some courage. The present neonatal rate is 64 per cent of the total infant death rate, the causes given being prematurity—roughly $\frac{1}{2}$; debility and like causes 1/10; malformations

1/10; birth injuries 1/20. The stillbirth rate has risen steadily 9 points in 5 years, "at the same time as the live-birth rate has consistently declined." (In all considerations of neonatal deaths and stillbirths we have to bear in mind that there are still variations in definition of the term "stillbirth.") Maternal mortality is recorded as 4.25, with an average during the years 1921-1925 nearly one unit above the average. Fifty-seven per cent of the deliveries occurred in hospitals. The average forceps delivery rate for New Zealand hospitals is 14 per cent of all cases delivered.

The department reports plans on foot for new equipment and accommodations in hospital service, a standardized aseptic routine, extended training for midwives, etc. and expects from all a decline in hospital mortality rate as a result.—*Pub. Health*, London, Dec. 1927.

Breast Feeding—Minneapolis puts out an interesting and valuable report on breast feeding. The summary of local factors influencing infant mortality is particularly good. We are somewhat surprised to see included these statements: "In Minneapolis city water need not be boiled to render it safe for babies," and "all milk distributed in Minneapolis is pasteurized or from certified cows," which would seem to indicate that boiling water and milk for babies is considered quite unnecessary in any case. The report does not state how many babies were receiving both bottle and breast feeding but says: "Breast feeding includes all babies receiving any breast milk." Methods being employed in the campaign are discussed. Here, as elsewhere early infant mortality has not been affected. Deaths under 1 month were 57 per cent of the infant deaths for 1926. (Compare 67 per cent for New Zealand.) The author feels that "more and more the application of breast feeding is proving that maternal milk secures for the baby a permanent foundation for

a healthy childhood."—Helen Chesley Peck, *Pub. Health Nurse*, Dec., 1927.

Influence of Pregnancy On Teeth—Another interesting contribution to this very important subject is presented in the December issue of the *Dental Cosmos* by Dr. Guttorm Toverud of the State Dental Institute of Norway. This article includes a fine summary of the work that has been done along this line in various countries as well as the results of the author's experiments on rats "to see if pregnancy even under normal nutritional conditions might change the chemical composition of the teeth." The conclusions presented are as follows:

1. Histological and chemical changes are found in bones of pregnant women.
2. Lowering in blood and saliva calcium are found during the latter part of pregnancy.

Both of these conditions may be the result of a faulty calcium metabolism caused by an insufficient intake of calcium, or by a disturbance in the function of some of the endocrine glands. Furthermore, this point of view is supported by:

3. Experimental studies showing that the mother during pregnancy has to give off some of her own calcium from the hard tissues when the intake is insufficient to cover the need of the mother as well as the need of the fetus.
4. The experiments on rats described in this lecture, which show that rats fed a calcium- and vitamin-deficient diet (also containing a toxic factor) during the gestation period developed front teeth of a very inferior chemical composition.

The practical conclusion which may be drawn from this preliminary study is: A liberal intake of lime corresponding to the content of about one liter of milk daily (1.2g. Ca) and a liberal intake of the vitamins necessary for the utilization of the lime, viz., uncooked fruit, green stuffs and milk (and cod liver oil), will be of invaluable help in conserving the teeth of the pregnant mother.—Dr. Guttorm Toverud, *Dental Cosmos*, Dec. 1927

Dental School Clinics in Germany
—The Association of German Municipalities recently published in its official organ the results of an investigation into public provision for the care of the teeth of elementary school children in its member cities. The general conclusion is that the cities are giving an increasing amount of attention to this subject.

The study covered 92 cities having a population of over 50,000. Fifty of the 92 cities maintain their own dental clinics for school children. In the cities not having municipal dental clinics other arrangements are made, such as examinations and treatment provided either at the university clinic or paid for from sickness insurance funds. In many cities dentists in private practice are engaged by the authorities to give dental care.

In addition to being provided in elementary schools, dental treatment is given in an increasing number of compulsory continuation schools. At the time of the investigation mentioned above at least 28 cities were providing such treatment.

The cost of this work is met almost entirely by the municipalities. In several cities subsidies are also given by social insurance funds. A very small fee is paid by the parents in some cities. —*Zentralbl f. Jugendrecht und Jugendwohlfahrt*, Berlin, Sept. 1927, p. 157.

Tetanus Following Vaccination Against Smallpox and Its Prevention

—Whenever the subject of vaccination is brought up some one is very apt to have a story to relate of a very sore arm having resulted from that procedure. As such stories circulate, additions are occasionally made and we finally learn that the arm was lost. These lost arms are exceedingly difficult to find. There is no denying the fact, however, that very sore arms do at times follow vaccination. The unfortunate part of the whole matter is that people are very apt

to blame the procedure itself for these results, and not the method employed in vaccinating, or the way in which the vaccination was or was not afterward cared for. Most, if not all, of the excessively sore arms are due to improper vaccination technic or to improper after care or lack of after care. Vaccination is a form of minor surgery and deserves the attention and care accorded any other minor injury.

The occasional cases of post-vaccination tetanus while relatively rare are a much more serious sequel. Among the thousands of vaccinations which must have been performed, only two such cases are known to have occurred in Massachusetts last year. In both instances, the cause was very evidently faulty after care.

In a recent number of *Public Health Reports* (Dec. 16, 1927), Dr. Armstrong of the U. S. Public Health Service presents the evidence, gained through case investigations and laboratory experiments, concerning post-vaccination tetanus. He concludes that such infection is due either to infected bunion pads used as dressings or to the presence of the specific organism at the site of vaccination, either at the time of vaccination or through subsequent contamination of the vaccination area. His summary is as follows:

1. Epidemiological evidence is presented which indicates that post-vaccination tetanus, when it develops, tends to follow severe primary vaccinations performed with large insertions and dressed with some type of shield or covering strapped to the site.

2. Shields and dressings are shown markedly to predispose to the development of post-vaccination tetanus in monkeys and rabbits vaccinated with virus artificially contaminated with *B. tetani*.

3. A proper vaccination is defined as one in which the insertion is not over one-eighth inch in its greatest diameter, made by some method which does not remove or destroy the epidermis. Such insertions treated openly, i. e., without the use of shields or dressings strapped to the site, have never, in so far as we are aware, been followed by post-vaccina-

tion tetanus. It seems probable that the adoption of these simple procedures of technic on the part of vaccinators, coupled with a proper warning to the vaccinated individual, or his parents or guardian, concerning the dangers of home applied shields and dressings, would eliminate tetanus as a complication of vaccination.

To carry out a proper vaccination as defined above, the following procedure is suggested:

1. The site should be the insertion of the deltoid.

2. Cleanse the skin thoroughly but gently with acetone or 70 per cent alcohol (denatured alcohol should not be used) and allow to dry.

3. Use the Kinyoun or multiple pressure method of insertion through a drop of virus expressed upon the skin: make horizontal pressure with the point of the needle 20 to 30 times. The skin should be held taut and the area of the insertion not over one-eighth inch in diameter. A new, sharp, flamed needle should be used. The virus is wiped off immediately afterward with sterile gauze.

4. After care—no dressing is applied at the time of vaccination or subsequently, unless an open lesion develops following the formation of the vesicle. Under such circumstances, a large antiseptic dressing is strapped loosely over the vaccination, the adhesive straps being applied well away from the vaccination site. Under no circumstances should shields or other forms of dressing than those specified be used, and such care should always be given under a physician's direction. The vaccination should be followed by the physician during its entire course, not only to determine the immunity status, but to insure the proper after care necessary to prevent complications.

—Charles Armstrong, *Pub. Health Rep.*, Dec. 16, 1927.

The Early Diagnosis and Non-paralytic Anterior Poliomyelitis— Much interest has been aroused in the recent outbreak of poliomyelitis in Massachusetts. In view of the confusion in regard to the nonparalytic form of the disease, the author discusses the early diagnosis based on a large number of observations during the summer. The typical onset and course of the acute stage is described.

The assumption that the disease may stop at any point in its development

offers an explanation for the abortive type, where there is a generalized infection with the virus of anterior poliomyelitis, which does not go on to localization in the central nervous system; the nonparalytic type where there is a demonstrable invasion of the central nervous system both by physical signs and lumbar puncture, but where no discoverable paralysis ensues; and the paralytic type where there is invasion and injury to the central nervous system, with the characteristic and oftentimes crippling paralysis, which gives the disease its interest and its dread.

The author paints a picture of the symptomatology and physical signs of the nonparalytic type and the pre-paralytic stage of the paralytic type which very often permits the making of a definite diagnosis.

A tentative diagnosis of poliomyelitis having been made, the diagnosis is confirmed by an examination of the spinal fluid. The pressure is usually increased, there is an increase in cells up to 700 or 800, and the fluid presents a ground glass appearance. The sum of this information makes the differential diagnosis not difficult.

The author points out the impossibility of determining whether or not a case will become paralyzed, as well as lack of information as to the ratio of paralytic and nonparalytic cases. He summarizes as follows:

1. In the present state of our knowledge the prevalence of the abortive case of poliomyelitis as previously defined must remain a matter of conjecture. It is the type of case more often heard about than seen.

2. The nonparalytic and paralyzed case are alike in their onset, and can be diagnosed accurately in the majority of cases in the absence of or before the occurrence of paralysis.

3. The nonparalytic case as defined in this paper probably does not constitute a very large proportion of the total number of cases.

—Eliot H. Luther, M.D., *Boston, M. & S. J.*, Dec. 22, 1927.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

ARE YOU SATISFIED WITH THE ANNUAL REPORTS YOU RECEIVE?*

OVER the desk of any organization executive pours a stream of annual reports. Some are glanced at, some read through, and occasionally there is one whose contents are studied with a searching eye.

Several executives decided in 1924 that these reports would be more valuable if it were possible to have more uniform methods of preparing them so that one organization might place its figures beside those of another, make trustworthy comparisons and draw conclusions therefrom. The committee which was later appointed prepared an outline and made a report in 1925 which resulted in the addition of new members to the committee to represent the smaller communities. At the 1926 meeting, it was decided that the report should be published in the professional journals asking interested workers to submit any further recommendations which they might wish to make. Such a summary appeared¹ in the *Public Health Nurse* of May, 1927. Apparently there is no desire on the part of workers to add to this material. It would be justifiable to assume that public health workers are satisfied with the reports they receive, or at least that they are basing their hopes for improved conditions on the apparent change that is taking place.

The trend in content of reports during

the past few years should hearten even the pessimist. After all, why should we expect changes in style only in the picture section of the report? The picture of a nurse, which appeared and reappeared as the frontispiece of a report from one of our large organizations in the years of 1912 and 1913, is in marked contrast to the one which appears in the picture section of this year's report from another large city organization. Our first reaction to these pictures is to laugh and to think how absurd it was to climb about on tenement stairs in skirts of such length. How much more attractive and comfortable our nurses appear in modern times, and how much more universal is a businesslike uniform in organizations all over the country. In the "hat pin age" there were many public health nurses who went about in the homes in ordinary street clothes. (See Newark, 1912.)

The change in fashion is quite significant of the changes which have taken place in the general content of the report. With the long skirts of those days we were apt to find the long narrative of the nurse's work and the long list of "donors," etc. Today, when modern advertising, moving pictures and radios have taught us that the public will only grasp what can be seen at a glance, we have the concise, business-like statement from the president and director, the single page of large-typed totals for statistical material and the balance of the report made up of well chosen pictures, all of which give a concise story of the work. (See Boston, 1925).

* This paper by Marguerite A. Wales, R.N., was presented as the Report of the Committee on Standard Forms for Annual Reports of Public Health Nursing Associations or Groups, to the Public Health Nursing Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

Prof. Ira V. Hiscock has stated in his admirable paper which appeared in the April, 1927, *Public Health Nurse*,² that a report must be prepared for four principal groups of people: the supporting public, the board which is responsible for management, the staff, other public health workers, etc.

Most of the supporting public will only be interested in the story which makes its appeal in a striking way—hence the resort to modern advertising methods. The board responsible for management will be interested in figures on the financial page and the statistics, with a brief story of growth and plans for the future. From the new topics creeping into the president's reports, referring to national public health projects, we see the effect of the layman's place in our public health organizations (see Toledo, 1926), and we can count more and more on a board which will understand our problems. The staff, of course, we should assume will be interested in the same sort of material as that prepared for "other public health workers." Until recently the fourth group, which represents the reader who studies reports with professional interest in comparative tables and development of programs, has been the most neglected one.

In the past, these comparisons have been difficult to make because of lack of uniformity in terms. What has been the distinction made between "cases" and "patients" in statistical reports? How should tuberculosis *contacts* be recorded? In an association doing child welfare work, and therefore carrying a large number of well children who could not be discharged, should the records be based on *admittances* or on *discharges*?

These problems brought about the appointment of this committee. The work of "defining terms" has been left to the Record Committee of the National Organization for Public Health Nursing, which has made up record

forms which are being tried out in many organizations all over the country.

During the years since the N. O. P. H. N. Visiting Nurse Service Study,³ organizations have been making much better analyses of their work and we begin to see a change in the annual report. Cleveland, we believe, was the first organization to introduce figures from a "time study" into the pages of its report. Immediately other organizations began to compare notes. "If Cleveland spends so much time on this or that phase of work, how do we compare?" they began to ask, and these questions gradually crept into print. Later, Detroit presented a comparative table from a number of organization figures which was very helpful. We find ourselves saying: "If Detroit spends 56.9 per cent of its time in maternity work, how much time per visit do their nurses average in the care of a maternity patient?"—and so on.

Today, we are getting a basis of study, and the annual report will come to be the exchange of program and general plan which will lead us to a better understanding of the city programs. With health departments using the *Appraisal Form* more and more and bending their efforts toward defining standards, surely the nursing organizations must work toward some means of comparing their work and how it fits into the city picture, and this can be greatly facilitated by a standard form of annual report. With this in mind, we shall review here the points which the committee agreed upon as desirable in an annual report.

The reports should contain a general report from the president or director stating the principal aims of the organization, based presumably on the needs of the community. The Visiting Nurse Association is the key group to study morbidity situations and much valuable data could be prepared by taking groups of diseases and trying to establish a mor-

bidity rate according to age. The layman who is giving his support to such work will find much of interest in figures which show just how far his money will go in meeting the community demands.

The report should contain an outline in brief of the various branches of the service instituted to carry out the aims; for instance, the statement here could contain information as to whether the organization carried solely a staff for acute sickness situations, or whether it included: acute sickness, chronic sickness, maternity, clinic service, health education, and public health teaching. Statistical material should be presented in connection with the various services; for example, the number of staff apportioned to each service (obtained from number of hours, for a generalized service); amount of time spent in each service; and per cent distribution of the entire work among the various services.

This might seem an appropriate place in which to enter a brief survey of the community facilities and a justification of emphasis on any one or more branches of the organization's work. The number of cases and visits should be listed in age groups and nationalities; the morbidity and mortality statistics by disease groups; the duration of visits and number of visits by diseases (see Dr. Louis I. Dublin's "Records of Public Health Nursing" for a uniform method of tabulation of statistics above mentioned). Reports should clearly define the organization's policy in regard to the content of a visit; that is, when a nurse is carrying a prenatal patient under her supervision, if this supervision is carried on by correspondence rather than by personal visits, it should be so stated.

There should be a statement of budgets and costs. The items of budget to be included and how these should be entered and defined are covered in the Report of the Committee to Study Visiting Nursing." Statistical material based on the suggestions of this report would af-

ford also a detailed study of the costs of various services if an organization were equipped to gather and tabulate this additional data.

In this connection, the following might be suggested as valuable and interesting where possible to obtain: time spent in each function which the nurse performs, that is, office, travel, assigned duties, clinic work, field work, and, further, time spent in different types of field work; costs of service time (using such a unit as the hour for a basis; from this could be readily computed the amounts expended on maternity work, on acute sickness visiting, etc.); type of work accomplished; number of visits by type. The report should include a statement of the future plans of work and recommendations for the progress of public health work in general.

In conclusion, then, we might say that while we find the annual reports of some organizations including just the type of figures needed to make comparisons easy, other organizations should be encouraged to follow this general outline so that workers all over the country may benefit by comparisons of work and programs.

Hourly Nursing—Hourly Nursing, or the appointment service plan, is being given considerable thought by Visiting Nurse Associations all over the country. There are at present four methods of administration in vogue. In certain cities, the entire service is carried by the visiting nurse staff, in others there is a joint scheme worked out with the central registry for nurses, in still others the registry carries the service alone, and of course there is the "free lance" nurse.

The Public Health Nurse for January, 1928, is publishing follow-up material on the study made by the Statistical Department of the National Organization for Public Health Nursing in August, 1927. This material includes an excerpt from Dr. Winslow's report* on the progress of the Grading Committee as given at the A. P. H. A. meeting in Cincinnati, and a bibliography on the subject, which we quote here. Other articles and discussions are to follow.

Buffalo Conference On Family Life in America—The Conference on Family Life in America, held in Buffalo in October, 1927, dealt with many problems closely related to the health of the family and individual—the meaning and use of leisure, spiritual factors in family life, the ideals of marriage and parenthood, and most interesting perhaps, the changing basis of family support and expenditure. This last was dealt with very ably by Paul H. Douglas of the University of Chicago. He said in part:

The family as a consuming unit will in all probability, despite certain obviously opposite forces, continue indefinitely. In the future, however, increasingly large numbers of men and women will earn their living as individuals within the family. This individualistic way of securing income, and the largely combined method of expenditure, present some interesting prospects.

Will the employed children contribute to a common fund? Many now retain their earnings and live on a far more expensive scale than others of their economic class. They are young, and spend for luxuries what is spent by others on necessities. This scale of living unfits them for marriage, and the proper physical and spiritual care of children. Another result is the added weight of responsibility on the mother and father, and younger children, who are often deprived of the basic needs in family life because the older children fail to pool their earnings. The most overworked and exploited members of society are the working-class mothers of two or more children. Even their food is often cut below the level of decency and efficiency. No labor laws have been enacted for them! Adjustment of wages to number of children supported has been suggested, but bears with it many objections. The writer feels strongly that bachelors and childless couples have not so great a demand on industry as the family, which is rearing the next generation, and which is therefore returning to the nation manpower of definite economic value.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Group Thinking Better Than One Mind—In building new words from certain given words a group did better than individuals working alone, as reported by Goodwin B. Watson, of Columbia University, at the recent-meeting of the American Association for the Advancement of Science. Dr. Watson granted that further investigations are necessary to ascertain whether groups are more effective in accomplishing more difficult tasks. The editor would call attention to the positive gains in many situations through group discussion *rightly conducted*. *Created Discussion*, revised edition, is a clear, untechnical guide in keeping group discussion from deteriorating into aimless talk. "It shows in sharp outline the principles by which any average group can open up an issue in ways to assure an orderly and searching procedure. Members of committees, conferences, and study circles will find in its pages new suggestions for making group experience rewarding."—*The Inquiry*, 129 East 52nd St., New York, N. Y. 63 pp. 50 cents.

Gains in 13 Years—"The American Social Hygiene Association, through its Division of Public Information, for 13 years has steadily developed and promoted ways and means for building up public opinion in favor of sound social hygiene measures. The results are apparent. Whereas, among most people, sex was formerly a subject discussed in whispers behind closed doors, social hygiene is now a leading topic of discussion in meetings and conferences every-

where. Where once it was difficult to get a hearing in schools and colleges, or before clubs and educational groups, today the association's staff of lecturers is engaged for months ahead. Our books are found in the regular stock of the average book-shop, thousands of requests for our pamphlet publications are received each month, and the *Journal of Social Hygiene* and the *Social Hygiene News* are available not only in libraries generally in this country, but abroad as well. There is a steady demand for motion pictures, lantern slides, posters and specially arranged exhibits dealing with social hygiene."—*Social Hygiene News*. "Public Information Number." 370 Seventh Ave., New York, N. Y. Nov. 30, 1927. *Free*.

"What Do You Think of It?"—Ask this question of the average individual and he will say that the annual report is "fine," the letter is "a winner," the meeting "was great." Most people do not like to criticise us and our products to our faces.

Getting small groups of people together to criticise frankly, to raise questions and to make suggestions is about the only method of getting at the honest judgments of the non-expert. And the sharing of such opinions stimulates the critical attitude toward our own material and stirs latent common sense which after all is enough to lead us to see many of the faults in our health education material.

Indoor Sport for Health Workers—Within a year or a little more six national and local New York agencies have made collections of health education

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

posters or of information about available posters, and several others have mimeographed lists on hand. Would it help to lessen duplication of effort if the editor of this department could announce when you are about to collect information or make up lists?

The National Health Library, 370 Seventh Ave., New York, N. Y., announces the compilation of a list of health education posters.

The National Health Library announces a revision of a list of health magazines of general interest and bulletins or house organs of national, state and local health agencies—principally of the public departments.

Copies of the National Health Library lists will be supplied upon request. *Free*.

The editor of this department announces the preparation of a list of national, state and local house organs and other periodicals in all health and other social and civic fields in the United States, Canada and other countries.

The editor announces a revision of lists of national, state and, to some extent, local agencies—health, social and civic—in this and other countries.

The compilers of the above lists will welcome coöperation.

Making a Survey Work—

No reform movement, or important change in the community's activities can be forced upon the community from the outside. Anything of permanent worth must come from a desire within the group for such a change or reform . . . Before the majority of the members of the community will have the same attitude toward any extensive change or reform, however, they will need to have the same insight into the local situation and the causes back of it, that the group of leaders who have been active in carrying on the survey have.

This insight into local conditions and activities and the possibility of improvement and greater efficiency will be reached by the majority of the community only when they have been given the facts in the matter. That is why the Publicity Committee has the most important work of the entire survey.

The object desired will never be reached by having published one or two formal reports

in the newspapers or a formal report in pamphlet form, no matter how valuable such a report may be. While these formal reports have great value, especially for comparative purposes and for the leaders of the various social agencies, they must be only a part of the general campaign of publicity which is carried on for the benefit of the local community.

In chapter on "Publicity" in *Technique of Social Surveys*, by M. E. Elmer. J. R. Miller, Los Angeles. Revised 1927.

Consultation with Specialists— Surveys and studies, investigations and reviews of many types are very common in the public health field. Frequently it is the department or volunteer agency of known efficiency and effectiveness that calls in a specialist or group of leaders in public health to look it over—a health examination, if you please, made for the same reasons as a physical health examination.

The same procedure is being followed in business and industry to a considerable extent. And now a writer in *Printer's Ink* argues for such an examination of the advertising department. See how the argument could apply to the publicity and educational work of a national, state or local health body:

What would have resulted? When a physician is treating a patient, the family or the man himself may worry over the lack of progress and begin to lose confidence. The doctor may be morally sure that he is doing all that can be done. But, if the case is critical, he often finds it to be good psychology to call in one or two other medical men and get their opinions. If they agree that the treatment is right, the patient and his friends are reassured and the doctor then has a fair opportunity to do his work. Doubtless the others can make certain helpful suggestions. Two or three heads are always better than one in medicine just as they are in anything else.

On the other hand, the consultation may develop something that had been overlooked, requiring the services of a specialist. In this case, the first doctor would naturally step aside.

Or perhaps there might be no dissatisfaction on the part of the patient or his family, but the physician himself might be worried over the progress of the case. He would be doing a wise and professional thing if, with the

consent of the family, he should call in a couple of other doctors and check over the case with them. Here the outcome would be substantially the same as before. If he were found to be on the right track, his confidence in himself would be increased and the patient's chances for recovery made better.

Such things are happening in the practice of medicine every day in every town.

Now That the Holidays Are Past—The time has come when many groups of health and other social workers might get together to talk over their annual reports, leaflets, meetings, etc. The New York Committee on Publicity Methods has already started a series of discussion meetings and self-clinics. To avoid speech making, to secure adequate group participation, and to have a friendly, intimate atmosphere, the sessions are limited to 20 or 25 people—the smaller number being preferable. The advance registration shows that two sessions each will be needed to handle some of the topics.

The New York Topics—Registrations have been accepted for the following topics:

- 1 Comparisons of costs of printing—Are we paying the right prices for what we get?
- 2 Problems in dealing with printers
- 3 Costs, qualities and uses of paper
- 4 Annual reports—a group clinic on reports of those present
- 5 The uses of dailies other than the metropolitan dailies
- 6 Our doubts or difficulties in dealing with newspapers
- 7 Press stories—a group clinic on press releases of those present
- 8 How can we evaluate results of our educational publicity?
- 9 How agencies are "Programming" their publicity
- 10 Comparison of functions included in publicity departments
- 11 Figuring costs of mail appeals
- 12 Sobs vs. reasons in money appeals
- 13 Difficulties in using outside publicity workers or bureaus and how the difficulties have been overcome
- 14 Film slides and continuous motion pictures
- 15 The uses of the multigraph and mimeograph

16 Problems of those doing state-wide publicity

17 Problems of those doing national publicity

The details on any topic will be sent to any one who wishes to organize a local group. Members of the Public Health Education Section of the A. P. H. A. who wish to attend some of the New York sessions will be supplied with registration blanks. Address: Committee on Publicity Methods, 130 East 22d St., New York, N. Y.

Baby's First Letter—The first letter received by most babies in Racine, Wis., comes from the Board of Health:

Dear little friend—

A happy birthday and many, many of them!

You think you are quite big, now that you are eating cereals, toast, butter and cooked fruits, besides your milk and orange juice; now don't you? And you have some tiny, white teeth, too.

What a big person you are getting to be! And just after this first birthday is the time to make your first visit to the dentist and to have a tooth brush all your very own just like the big ones Daddy and Mother have.

And while you are out to see the dentist, go to visit your doctor, too, or the baby clinic and ask all about the treatments which will keep you from having smallpox and diphtheria. Maybe the treatments can be started that very day—the sooner they are begun, the safer you will be.

Keep on growing strong, little friend, by eating the good things Mother gives you and sleeping 15 hours of the 24 in fresh air. Oh yes! And stay away from those people who have colds—colds may mean all kinds of sickness to you.

Again, I wish you a happy birthday!

Yours for health,

(Signed) W. W. BAUER, M. D.,
Commissioner of Health.

The letter is printed on a pleasing rough finish paper, 7- $\frac{1}{4}$ by 10 inches, with envelope 7- $\frac{1}{2}$ by 4 inches. Delivery is made by health department nurses on each first birthday. Says Dr. Bauer:

Births as they are reported, are indexed in a tickler date file a year ahead, and the delivery of the greeting is always carefully timed for exactly the baby's birthday, except that Sun-

day and holiday babies receive theirs on the last business day before the birthday. The cost is \$43.00 in quantities of fifteen hundred. For us this is a little more than a year's supply.

Linoleum Blocks Again—More effective than photographs for many illustrations in much health education and publicity are linoleum blocks. "Modern linoleum block printing is, in reality, the revival of one of the most ancient forms of printing."

How the Cornell College of Agriculture makes effective and inexpensive short runs of posters was told in the November, 1927, issue of the JOURNAL.

An illustrated working guide for making linoleum blocks for various printed forms appears under "Making Posters from Linoleum Blocks," by C. W. Smith, in *The Poster*, 307 South Green St., Chicago, Ill., Nov., 1927. 30 cents.

Detailed information is given in a delightful volume, *Essentials of Linoleum-Block Printing*, by Ralph W. Polk. Manual Arts Press, Peoria, Ill. 1927. 60 pp. \$2.00. Many a health worker would find that "the making and printing of linoleum blocks is intensely interesting work," and that "it is a real joy to create an original design, carve it in linoleum, and to obtain printed copies of it." Limited editions can be printed by hand, or an old-fashioned letter press can be used. The high school printing office may already be using the new-old art, and commercial printers can run the blocks in your printing jobs. Quite a few illustrations for health use can be copied, and probably art instructors can be enlisted. *We hope to exhibit a collection of linoleum illustrations at Chicago in October, 1928.*

RADIO

For dates of talks over station WEEI, address Mass. Society for Mental Hygiene, 5 Joy St., Boston, Mass.

There was little tuning off by those not discouraged by the dull title, "Heart

Disease," who listened in on Dr. M. M. Myers at Station WHO, Des Moines, Ia. "A Doctor, a Nurse and a Ford Car" would have been a better title. In The Campaign, Iowa Tuberculosis Assn., Des Moines, Ia.

"Three talks a week on guides to health and safety, embracing in detail the subjects of home hygiene, first aid and life-saving," were put on the air by the Pittsburgh Red Cross Chapter "in the 1926 enrollment, in addition to educational talks on Home Service, Junior Red Cross and general activities. Beginning October 4, some five weeks before Armistice Day, and ending on November 22, at the close of the campaign, these health talks were not on abstractions but on subjects of immediate interest to every parent with a receiving set. They included such matters as care of the baby, small child and school child; the cause and prevention of common ailments, proper diet, emergency care and treatment of the injured, and water safety and rescue work, as taught by the chapter staff. As a result of these radio addresses, the chapter received many inquiries from persons desiring to join classes. In any case, public attention was directed to the health education work of the Red Cross."—*Red Cross Courier*. Nov. 1, 1927.

For ammunition in dealing with radio stations, see the following:

"Broadcasting Buncombe" about health. Editorial review. *J. A. M. A.* Nov. 19, 1927.

"Station UCFL." Editorial on health exploitation. *Hygeia*. Dec., 1927.

"Can Radio Be Rescued?" *New Republic*. Oct. 26, 1927. The general situation and how it came about.

A REQUEST FROM BRAZIL

Dr. Euvaldo Diniz Gonçalves, Rua Morechal, Bittencourt, n. 15, Bahia, Brazil, writes for "some information about popular instruction of adult groups in matters of health; that is,

health publicity or health propaganda. As director of the division of health education in the state department of public health, I am interested to know the service done by the similar offices of that country. Will you have the kindness to ask for me some educational material and information regarding the activities of the state departments?"

Will some state departments write, and some local, state and national agencies send him examples of educational material? Please tell the editor when you have done so.

EDUCATIONAL MATERIAL

Public health workers or at least those who use health posters are invited to help the National Health Council make up a list of posters and placards available nationally. Ask the Council at 370 Seventh Ave., New York, N. Y., to send a copy of the "preliminary list" and then quickly write them your suggestions as to the information given in the list, and the omissions or inclusions to which you object.

An 8-page folder for mothers: Keeping the Well Baby Well. Children's Bureau, Washington, D. C., 1927.

Texts for teaching and materials for use are listed in *A Catalogue of Supplies and Books on First Aid and Life Saving*, 1927 (revised). American National Red Cross, Washington. *Free*.

The "what are Strep-to-coc-ci?" cards of the Onondaga Health Assn., Syracuse, N. Y., are being used by the Tuberculosis Society of Detroit, Mich.

A revised edition has been issued of *Plays and Pageantry*, the list of health plays recommended by the National Health Council. *Free* of National Tuberculosis Assn., 370 Seventh Ave., New York, N. Y. Gives synopses of 25 plays which are sold at 10 to 25 cents a copy. They are arranged in age groups: 5-7

years of age, 7-10, 10-12, 13-18, for older persons.

Eight pages of posters in color, 2 on prenatal care (from India and Russia) and 6 on child health (from China, Japan, France, etc.), accompany "Teaching Prenatal Care by Means of Posters," by Stuart B. Blakely. *Hygeia*, 535 North Dearborn St., Chicago, Ill., Dec., 1927. 25 cents. "The Russian prenatal posters are full of action, striking in color, beautiful in design, with the printed matter subordinate and even decorative."

A Long Life and a Merry One, by D. B. Armstrong. Metropolitan Life Ins. Co., New York, N. Y. *Free*. Reprint from *North American Review*. "The significant thing for the average man of today is not only that he lives 30 years longer than his forefathers of 1789, with much less illness and much more comfort, but also that he can today add 10 or 20 additional years' to his life span."

Fifteen enclosures and four mimeographed pages (plus colored mimeographed cover) of ideas and references to material for use by New York local tuberculosis workers make up the second issue of *Do You Know?* Frances H. Meyer, Health Information Service, State Committee on Tuberculosis and Public Health, State Charities Aid Association (14 words in that name!!), 105 East 22d St., New York, N. Y.

If you wish to locate popular or scientific material on cleanliness—in the home, school, office, factory or community—it is likely to be listed in *Cleanliness: A List of Recent Publications*. Cleanliness Institute, 45 East 17th St., New York, N. Y., 1927. 30 pp. *Free*. Special attention is given to school material, stories, free or inexpensive material, both general and for school use. The binding of this mimeographed pamphlet may suggest a usable wrinkle.

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR.P.H. *

A MAELSTROM of measures descended on the Seventieth Congress between December 5, when it convened, and December 21, when it took its holiday recess. Out of some 8000 bills and resolutions introduced in both houses of Congress during the first two weeks of the session, a score or more are of considerable interest to sanitarians.

The Parker Bill—Without a change, Hon. James S. Parker of New York has reintroduced his bill for the coördination of federal health activities. It is now known officially as H. R. 5766, a number which should be kept in mind. This measure was introduced on the opening day of Congress and was referred to the Committee on Interstate and Foreign Commerce, of which Mr. Parker is chairman. This committee has referred the bill to a subcommittee headed by Hon. Carl E. Mapes of Michigan, which rather unexpectedly held hearings on the measure in January. Considerable opposition developed against the first section, giving the President power to transfer bureaus to the Public Health Service. The subcommittee is said to have deleted this section and reported the bill favorably with this and some other changes. At the proper time sanitarians will be asked to communicate with their Congressmen about it, as this measure has been indorsed by every leading national public health agency.

The Ransdell Bill—Senator Ransdell of Louisiana has reintroduced his bill for a national institute of health and it is now S. 871. This bill, which has been referred to the Committee on Commerce

of the Senate, is similar to the Parker Bill, but has an additional section authorizing an appropriation of \$10,000,000 for a national health institute, which would be established in the Public Health Service. The idea is sound and the bill has been indorsed by the A. P. H. A.,† but because of the appropriation feature, it may have a more precarious legislative course than the Parker Bill. This bill has also received approval from the American Chemical Society, and the Chemical Foundation has issued a pamphlet by Charles H. Herty entitled "The Ultimate Mission of Chemistry: Good Health," which contains a strong plea for the passage of Senator Ransdell's bill. Hearings on this bill are scheduled for the middle of March.

The President's Message—The Annual message of the President, sent by Calvin Coolidge to be read at the beginning of Congress, contained nothing at all on the subject of national health.

In transmitting the budget for the next fiscal year the President did take occasion once again to decry the system of federal subsidies to the states. He pointed out that federal interference in state functions can never be justified as a permanent policy even though it may be warranted by an emergency. "As shown in the Maternity and Infancy act," says Mr. Coolidge, "when once the government engages in such an enterprise it is almost impossible to terminate its connection therewith."

T. B. and V. D.—Any World War veteran afflicted with tuberculosis who brings such fact to the attention of the Veterans' Bureau prior to September 1, 1928, would be presumed to have acquired the disease in the service, according to

* Correspondence to the associate editor may be sent to him as follows: c/o The Borden Company, 350 Madison Avenue, New York, N. Y.

† See Resolutions, *A. J. P. H.*, Nov., 1927, p. 1163.

a bill, H. R. 5477, introduced by none other than Mr. Blanton of Texas. This measure would extend the present time from January 1, 1925.

A veteran who contracted a "social disease" while in the service would also be entitled to treatment under the terms of this bill, and this regardless of whether the disease was due to misconduct or not.

Another bill, H. R. 261, would grant federal hospital treatment to postal employes suffering from tuberculosis, nervous diseases, or mental occupational ailments.

A Federal Board of Alienists—A United States Board of Alienists, to be composed of twenty well qualified physicians, paid salaries of \$25,000 a year each, is proposed by Representative Black. This bill, H. R. 7936, states that the duties of the board would be to diagnose and treat mentally deranged veterans, study mental diseases generally, recommend a code of ethics for alienists, and inquire into insurance company methods of dealing with insanity. A modest appropriation of \$5,000,000 would be authorized for these purposes.

A Federal Safety Division—The present U. S. Bureau of Labor Statistics would be augmented by the creation within it of a Division of Safety, according to S. 1266, introduced in the Senate by Mr. Shortridge. This division would collect statistics on industrial accidents and analyze them, study labor safety plans, and investigate all phases of occupational hazards and diseases and their prevention. There is a proviso in the bill to the effect that such work shall be undertaken in coöperation with other federal and state agencies and no studies which are already being conducted shall be duplicated.

The work of the Bureau of Labor Statistics is described in detail in the *Monthly Labor Review* for December, 1927, 30 pages being needed for this

article. Among the activities of interest to sanitarians are those dealing with industrial safety codes, the industrial accident prevention conference, industrial hygiene, and the elimination of the manufacture of fireworks containing phosphorus. In the field of industrial hygiene the work includes publication of occasional bulletins dealing with industrial poisons or diseases; a review of current medical literature as it relates to occupational hazards, which is published each month in the *Monthly Labor Review*; and replies to many inquiries regarding specific poisons or hazards from gases, dusts, and fumes. Recent bulletins have been published on lead poisoning and health conditions in the printing trades.

Other Health Legislation in Congress—Among the other bills of significance to sanitarians are: S.1267, to extend medical and hospital relief to retired officers of the Coast Guard; H. R. 16, to regulate osteopathy, and H. R. 5763, to regulate chiropractic in the District of Columbia; S.762, to provide for a sanatorium at Claremore, Okla.; S.1602, to amend the opium importation act; S. 1865, to provide for the protection of municipal watersheds within the national forests; H. R. 5747, to authorize admission to naval hospitals of dependents of officers and enlisted men in need of hospital care; H. R. 5604, for additional hospitalization for veterans; H. R. 7951, to control diploma mills in the District of Columbia; and H. R. 487, to prevent the manufacture, sale, or transportation of adulterated, misbranded, poisonous or deleterious foods, drugs, medicines, and liquors.

Physicians in Congress—If the biographical data in the annual Congressional Directory is dependable, there seem to be only 8 physicians and 3 dentists among the members of the Seventieth Congress. As usual, the lawyers predominate, with a few farmers and business men among the elect.

The only physician in the Senate is Dr. Royal S. Copeland of New York, though Senator Woodridge N. Ferris of Michigan studied medicine for a year or two. Senator Henrik Shipstead of Minnesota is a dentist.

In the House of Representatives there are 2 M. D.'s from New York, Dr. John J. Kindred, who has been in Congress for five terms, and Dr. William I. Sirovitch, who is there for the first time. Dr. Kindred is also a lawyer. The other physicians include Dr. Frank P. Bohn of Michigan, Dr. Ed. M. Irwin of Illinois, Dr. William T. Fitzgerald of Ohio. Dr. J. Howard Swick of Pennsylvania, and Dr. John W. Summers, of Washington. There are also 2 dentists, Dr. R. O. Woodruff of Michigan and Dr. Frank Crowther of New York. Representative Stephen G. Porter of Pennsylvania studied medicine for two years but thought better of it and became a lawyer.

Caustic Poison Law now in Force—When the President approved the First Deficiency Appropriation Act on December 22, funds were made available for the enforcement of the Federal Caustic Poison Act, which became a law on March 4, 1927. The administration of this law for safeguarding the distribution and sale of dangerous corrosive and caustic acids and alkalies in interstate and foreign commerce is entrusted to the Department of Agriculture, acting through the Food, Drug, and Insecticide Administration.

Legal Use of School Health Records—Can school health examination records be used as court evidence? Are these records an open book for anyone to refer to at will? Has any legislation been passed anywhere which protects the schools from the use of these records by out of school agencies? These questions have been submitted to us by a student at Teachers College in New York.

It is the general rule in the law of evidence that, in the absence of a specific statute to the contrary, relevant public documents may be admitted as evidence in courts of law. School records are public documents and authentic health reports, submitted by physicians as part of their school duties, would be admissible as evidence. It is in the interests of justice to secure all pertinent facts bearing on litigation.

Whether school health records are open to the public for general inspection would depend upon local policies and rules. Public records are usually public, unless a law says they shall not be. Health records in schools ought to be open only to those who have a legitimate interest in them.

As to the existence of legislation on this subject, it would be possible to answer this question only after an examination of state codes. The associate editor would be pleased to learn of any statutes which deal with this important point.

Enjoining a Laundry as a Nuisance—A laundry which emits noises and odors, blocks sidewalks, and deposits soot and grease has been held to be a nuisance in California, *Williams v. Blue Bird Laundry Co.*, 259 Pac. 484. Instead of closing the laundry, however, the court upheld a decree enjoining the Blue Birds from operating in a manner deleterious to health. That the laundry had been a going concern for ten years in the same place was held not to stop nearby residents from suing to enjoin it from causing a nuisance.

Tests for Cod Liver Oil—The national government will soon take steps to remove from interstate commerce all cod liver oil which is misbranded or adulterated. A biological examination conducted under the auspices of the Food, Drug and Insecticide Administration has shown that many of the cod

liver oil preparations advertised to contain vitamins A and D were virtually devoid of A and sparse in D. Since cod liver oil is now so widely used to prevent and cure rickets, this is a wise measure by the government.

Additional evidence of the value of sunlight in preventing and curing rickets is presented in a news release sent out by the U. S. Children's Bureau on December 12, 1927. It is pointed out that children in Porto Rico, where there is abundant sunlight, seldom have rickets, a fact confirmed by examinations of 600 infants on this island.

Miscellaneous Items—In Virginia a court has held that a city has the right to adopt reasonable and necessary health regulations, *Etheredge v. City of Norfolk*, 139 S.E. 508.

Compulsory insurance against tuberculosis is provided in a decree approved

in Italy in October, 1927, according to *Child Welfare News Summary* for December 17, 1927.

A study of juvenile delinquency is recommended by the chief of the U. S. Children's Bureau, who urges that a division be created in the bureau for that purpose.

Anthrax is still a danger in different industries, according to the U. S. Bureau of Labor Statistics, which calls attention to 7 fatal and 75 non-fatal cases of an industrial origin reported in Pennsylvania from 1922 to 1926.

Midwife supervision in various foreign countries is described by Dr. George W. Kosmak in the *Journal of the American Medical Association* for December 10, 1927. In the same issue Dr. S. Josephine Baker reports that 16 states have laws making puerperal septicemia a reportable disease. Her article is on Maternal Mortality in the United States.

CONFERENCES

February 6-8, Council on Medical Education and Hospitals, A. M. A., Chicago, Ill.

February 6-8, Federation of State Medical Boards of United States, Chicago, Ill.

February 14-16, Engineering Institute of Canada, Montreal, Can.

February 16-18, Mid-West Conference on Child Study, Chicago, Ill.

July 8-13, First World Congress of Social Workers, Paris, France.

July 16-21, Thirty-ninth Congress Royal Sanitary Institute, Plymouth, England.

BOOKS AND REPORTS

Interpreters of Nature—Essays by Sir George Newman, K. C. B., M. D., Hon. D. C. L., LL. D., New York: Oxford, 1927. 296 pp. Price, \$4.50.

All of us are familiar with the medical writings of Sir George Newman, who is justly regarded as one of the outstanding public health men of the world. It comes as somewhat of a surprise to many of us to find in this book a series of essays, some of which we would hardly have connected with medicine or the history of medicine. The author has shown the extensive knowledge with which we are so familiar, and in addition has given us a charming book made up largely of biographies of well-known men, though very few people would expect to find Keats included in this group. He is known to most of us only as a poet, and not as an apothecary or medical student, though we are told of certain discoveries which were made familiar to us eighty years later by the great Metchnikoff.

In such a book, it is hard to select any one or more essays for especial praise. Some readers had the honor of knowing Pasteur, while a large number knew the late Sir William Osler. It may be presumed that a great many readers will turn first to one or the other of these two essays. However, every medical man worthy of the name knows of the great work done at Padua, and the contributions to medicine of Sydenham, Boerhaave, and John Hunter. There is not an essay, nor even a page in any of the nine essays contained in the book, which is not worthy of careful attention. The style of the writer is exceptionally good, and the book as a whole can be heartily recommended both to the medical profession and to all who are interested in the advancement of medicine

or of mankind. The reading of such a book is not only extremely informative, but gives to the busy man a delightful change from the routine of his labors.

We would like to see added an essay on the life of that Prince of English physicians, Sir T. Clifford Allbutt, and a sub-title which would give a better idea of subject-matter of the book.

M. P. RAVENEL

Review of the Report of An Investigation of the Pollution of Lake Michigan in the Vicinity of South Chicago and the Calumet and Indiana Harbors 1924-1925—By H. R. Crohurst, and M. V. Velde. Public Health Bulletin No. 170. Washington, D. C.: U. S. Public Health Service, 1927. 134 pp.

This survey, which was conducted over a period of one year, October 1, 1924, to October 1, 1925, was made in coöperation with the Sanitary District of Chicago, the Chicago Department of Health and the State Departments of Health of Illinois and Indiana. The report contains 134 pages, with numerous tables and diagrams illustrating the results of the survey. The studies show gross pollution of the waters at the southern end of Lake Michigan by industrial wastes and sewage largely from sources in northern Indiana, especially from the U. S. Ship Canal at Indiana Harbor. The Calumet River was also found to be a factor in the lake pollution. The degree of pollution is such as to constitute a serious hazard to not only the public water supplies of Hammond, Whiting and East Chicago, Indiana, but at times the Chicago supply obtained from the Dunne and 68th Street cribs.

The influence of wind on the travel

of pollution in the lake is strikingly illustrated by diagrams.

The industrial waste problem is largely one of emulsified oils and tarry acid wastes from refineries and steel mills.

It is unfortunate that this survey did not cover a longer period, as the year studied was one of sub-normal rainfall. It is a valuable document and should be in the library of all sanitarians.

ARTHUR E. GORMAN

A Manual of Veterinary Bacteriology—By Raymond A. Kelser. *Baltimore: Williams & Wilkins*, 1927. 500 pp. Price \$5.50.

Major Kelser has attempted to fill a need by producing a textbook dealing with the microorganisms which are pathogenic for animals. Several recent textbooks on animal pathogens have appeared in the German and French languages, but nothing new in English has appeared in recent years. The book, therefore, fills a real need in teaching bacteriology to veterinary students, and as a reference work to those engaged in work on animal diseases.

The book is divided into 11 parts which are designated as follows: 1. Bacteria, Their Morphology, Physiology and Classification, 2. Bacteriological Methods, 3. Infection and Immunity, 4. Pathogenic Organisms of the Class Schizomycetes, 5. Pathogenic Fungi, 6. The Protozoa, 7. The Filterable Viruses, 8. Serology, 9. Hematology, 10. Preparation of Veterinary Biological Products, and 11. Bacteriological Examination of Milk and Water.

The author has adopted *in toto* the classification and nomenclature of Bergey, and apparently has relied on Bergey's work in large part as a guide in compiling the list of pathogenic organisms since several errors in Bergey have been perpetuated and identical omissions of important organisms have been made. The older names of organisms are given as synonyms and these are properly in-

dexed; hence it is possible to find old friends in the book even though they are disguised under unfamiliar terms.

The subject matter of the book appears to be accurate and up-to-date. The list of organisms described is reasonably complete although such important organisms as the *Vibrio fetus*, the *Corynebacterium pyogenes* and the *Bact. viscosum-equi* are overlooked. The chapter on the Preparation of Veterinary Biological Products is unique in a book of this kind and will prove useful to many.

It appears to the reviewer that the section relating to the bacteriology of milk has been inadequately treated. Veterinary students of the present day have need of a much broader knowledge of this subject than is given.

The book should be of value to all persons who are interested in infectious diseases of animals and in those diseases of man which are transmissible from animals. It represents the most compact and accurate descriptions of the organisms of these diseases which are available in English.

W. A. HAGAN

Clinical Application of Sunlight and Artificial Radiation, Including Their Physiological and Experimental Aspects, With Special Reference to Tuberculosis—By Edgar Mayer. *Baltimore: Williams & Wilkins*, 1926. 468 pp. Price, \$10.00.

This imposing volume upon the relation of light to disease reviews the evidence to determine whether light has earned a place in the treatment of disease; surveys modern methods and applications of light, both natural and artificial; and is undoubtedly the most complete work of its nature in the English language. The book is dedicated to "Edwin R. Baldwin, M. D. of Saranac Lake, N. Y., investigator of tuberculosis, teacher, and inspiring advisor."

The subject of light as a therapeutic agent now has a voluminous literature

and a thorough review is made in the present work. The writer's personal experience has had to do especially with the use of the mercury-quartz light, but also with the carbon arc and sunlight in clinical tuberculosis at Saranac Lake. Where phases of the problem have not come within the experience of the author, the work of others has been drawn upon liberally. A study of X-ray therapy is also included.

Chapter headings and certain sub-headings appear as follows:

- I. Introduction and historical
 - II. The nature of radiation, including analysis of sources, interaction, and luminescence
 - III. Some fundamental considerations on the action of light in animal and plant life
 - IV. The action of light on growth and nutrition, including germination, phototropism, and the analysis of light action and metabolic changes
 - V. The effect of radiant energy upon bacteria and related biological products
 - VI. Physiological action of light, including radiant heat, its penetration, the phenomena of erythema; and the effects upon special organs and functions
 - VII. The skin as an organ
 - VIII. The sensitization of tissues to light
 - IX. Some experimental studies (including valuable contributions by the author upon experimental tuberculosis in lower animals, and a summary of the work of others)
 - X. The influence of climate on solar radiation
 - XI. The clinical application of solar- and arotherapy including air baths, heliotherapy, etc.
 - XII. The sources of light used in therapy, with discussion of the various forms of carbon-arc lamps, the use of the mercury-quartz and tungsten lamps and their comparison
 - XIII. Clinical studies with artificial light
 - XIV. The dosage and technic in the clinical use of artificial light
 - XV. Indications and contra-indications for irradiation, both natural and artificial, and in various forms of tuberculosis
 - XVI. The X-ray treatment of tuberculosis in various organs and parts
- Appendix — This includes special papers upon the influence of light on biological reactions, chemical reactions, photosynthesis, the action of light on carbohydrates, protein, lipoids, oxida-

tion and reduction, and ferments, and the theory of light action.

A bibliography is included consisting of some 2500 authoritative sources of information in the field. An author index lists those whose works are cited in the present book. The subject index given has been found by the reviewer to be quite complete. Repetition of statement and thought occur occasionally from chapter to chapter but in such a manner as to really add to the value of the work.

The book is profusely illustrated with graphs, diagrams, and tables, and contains 37 full-page plates, each with ample caption and legend. The work makes absorbing reading to anyone interested in the subject. Dr. Mayer has truly contributed an encyclopedic production of highest authority to the field of light therapy.

EMERY R. HAYHURST

Textbook of Bacteriology—William W. Ford, M. D. Philadelphia: Saunders, 1927. 1069 pp. Price, \$8.50.

A useful reference book but not a textbook in the sense that it can be put into the hands of students. The author has evidently spent a number of years in the collection and compilation of the material included. The book is divided into 6 parts. Part I is entitled "General Bacteriology" and deals with methods of observing and cultivating bacteria. The number of stains and media given is more than sufficient for most laboratory purposes. Part II is called "Systematic Bacteriology." This section takes up more than half of the book and is by far the most valuable portion. The classification of bacteria suggested by the Committee of the Society of American Bacteriologists of which Professor C.-E. A. Winslow was chairman is followed. No mention is made of *Bergey's Manual*. This omission will doubtless be regarded by some bacteriologists as a recommendation for Dr. Ford. The scheme of

classification as given lends itself to easy use by the student attempting to identify an organism. If Part II had been published alone, it would represent a real contribution. Parts III and IV deal with the distribution of bacteria and with infection and immunity. Much of this material is brief and inadequate and is certainly not up to date. In fact, the reviewer has failed to find a reference in the entire book later than 1924. Part V contains descriptions of the Spirochetes, and in Part VI diseases of unknown etiology are discussed.

The book is profusely illustrated with plates made under the author's direction. These are a real asset.

JOHN F. NORTON

American Illustrated Medical Dictionary—*The terms used in Medicine, Surgery, Biology, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Medicine, and kindred branches*—By W. A. Newman Dorland, M. D., Philadelphia: Saunders, 1927. (14th ed. rev.) 1388 pp. (319 ill., 107 in colors). Price, \$7.00, Thumb Index \$7.50.

In reviewing a dictionary, one is always reminded of the countryman who undertook to read one, and in commenting on it, said: "I found it very interesting, but it changed the subject too often."

It is manifestly impossible to examine every word, and one can only judge of a dictionary by looking up a number of test words.

This dictionary has gone through fourteen editions, each of which has been favorably reviewed and all of which have stood the test of time. The present edition maintains the high standard set by the author, and certain typographical errors of the preceding one have been corrected.

It is beautifully printed on light paper, and is very free from errors. A number of new words have been added, which

the rapid growth of the science of medicine and its allied branches has made necessary. On the title page the name of Dr. E. C. L. Miller, Professor of Bacteriology and Biochemistry at the Medical College of Virginia, appears as collaborator.

The work can be recommended as one of the most useful and complete of its type on the market. M. P. RAVENEL

Towards Health—By J. Arthur Thomson, M. A., LL.D., New York: Putnam, 1927. 361 pp. Price \$2.00.

One always looks forward to the appearance of a book by the author with more than usual pleasure, as there are few writers who have so much sound knowledge or who can put what they have to say in such an attractive manner.

The present volume is unlike any from this author with which we are acquainted, and we cannot help thinking that he is not at his best in this new field. His object is to explain health from the biological standpoint, and expound the fundamental principles involved. To attain this aim, he has evolved what he calls the "biological prism," "Organism, Function, Environment," which he translates into the common words, "Folk, Work, and Place."

He holds very correctly that throughout the whole of life, good health makes for good morals and good manners, and that in every period of life, health is of the utmost importance. During childhood, adolescence, maturity and aging, health must be earnestly sought, though he properly gives a warning against becoming absorbed in the pursuit of health, in season and out of season, and draws the moral that we should "covet the best gifts and health will be thrown in."

The last chapter, "Vis Medicatrix Naturae: A Summary," emphasizes nature's power and methods of cure, speaks of the small amount of disease in "Wild Nature" as compared with that seen in

man and domestic animals, the absence of senility in wild animals, and gives some explanations of the facts. Civilization and domestication, with their sheltering influences, and the balking of natural selection, are chief causative factors.

The book had its origin in a series of popular Saturday Evening Lectures, given yearly by members of the Medical Faculty of the University of Aberdeen. They are known as the Farquhar Thomson Lectures, the object of the Trust being to promote the cause of health among the people.

One can always read what Professor Thomson writes with profit and pleasure. The book is beautifully printed on light paper and well made up. M. P. RAVENEL

Dental Education in the United States and Canada—A Report to the Carnegie Foundation for the Advancement of Teaching—By William J. Gies (Bulletin No. 19). New York: The Carnegie Foundation, 1926, 692 pp. Free upon application to the Foundation.

This report maintains the high quality of the earlier bulletins on education issued by the Carnegie Foundation. It is sound, comprehensive, and thorough. The last 450 pages of the book present detailed facts concerning each of the dental schools in the United States and Canada. The first 242 pages deal with the professional, public health, and educational problems of dental education.

The author presents a fascinating story of the history of dentistry and its emergence from prehistoric customs. He pictures the early days of unscientific dentistry, the early belief of physicians and laity that the teeth were not related to health, the refusal of a medical faculty in 1839 to develop dental education under medical auspices on the ground that "the subject of dentistry was of little consequence," the development of independent dental schools and their later

elevation to the rank of other professional schools in the universities of the country. It is made apparent that dentistry is becoming more medical in both training and perspective. Yet dentistry is distinct. The dentist is not allowed to practice medicine and the physician is not allowed to work upon the teeth without a special or dental license. The author points out that the development of dentistry into the equivalent of an oral specialty of the practice of medicine requires still broader definition, scope and educational opportunity. He believes that dentistry cannot be superimposed upon a medical education because of the large number of years required in training and because of the digital facility required in dental practice and demanding extensive clinical training.

The suggestion is made that dental education should be based upon a pre-dental training of 2 years in college, that it should consist of 3 years of undergraduate professional training which would equip the student for general practice, and that an additional or a special graduate year should be offered leading to specialization. Several of the best dental schools have already gone upon essentially this basis.

The report discusses: the statutory regulations relating to dental practice; the types, number and distribution of dental practitioners; the deficiency of dental service for negroes; the regulation of dental schools by professional organizations; the curriculum, equipment and research of dental schools. The proposed general reorganization of dental education, with an improvement in the nature and quality of instruction, better clinical service and financial support, is clearly presented. Dental education in Canada is given the same type of treatment as that in the United States.

In the excellent section on General Views and Conclusions (Chapter XII)

the report summarizes from a broad, public health viewpoint: the problems of the relation of the teeth to health, the prevalence of dental disorders, the deficiencies in oral health service, the present failure in preventing dental disorders and the main requirements for the improvement of oral health service.

C. E. TURNER

Keeping Well—By Kate Platt, M. D., B. S. London: Faber & Gwyer, 1927. 246 pp. Price, \$1.25.

Among the large number of books on the general subject of health written for the lay public, there are few that we can commend more heartily than the present. It is conservative and essentially sound, emphasizing the fact that our most successful efforts will be in assisting and directing nature, rather than indulging in drastic treatments, and running after fads. We like particularly the emphasis laid on giving nature a rest in the way of holidays, which, as the author says, bring about a readjustment of mind and body and allow nature to express herself in ways which are often suppressed. The necessity of frequent short holidays, and longer ones occasionally, has been emphasized recently in this country as a means of preventing high blood pressure. Certainly the results are all to the good.

One minor criticism may be made. The author speaks of a poor complexion as being evidence that "the condition of the blood is unsatisfactory." There is little doubt that many people will construe this to mean that so-called blood purifiers must be taken, though the context shows that good feeding is the point involved. In many cases of pimples and boils there is no evidence that the blood is at fault.

The book is of convenient size and well printed on the light paper which the English are so fond of using. It is readable as well as sound. M. P. RAVENEL

The Organization and Administration of Health Education in the Secondary Schools of the United States—By Fred Lea Stetson and Frederick W. Cozens. University of Oregon Publication, Vol. 1, No. 2, Education Series, June, 1927.

This is a very useful compilation of the important facts regarding health education in secondary schools of the country, as determined by statutes and administrative measures. The legal basis, the character and extent of the supervision, and the relation of the program to physical training and other school activities are summarized; and there are recommendations pointing out the needs as indicated by the survey. There is a bibliography of some sixty titles. One is impressed by the wide range of practices in the different states and the almost universal need for a critical re-examination of what is being done for health education, as well as for a critical restatement of objectives.

B. C. GRUENBERG

Tuberculosis in Infants—By M. Alice Asserson, M. D. New York: New York Tuberculosis and Health Association. 378 pp.

This report of the Children's Service of the N. Y. Tuberculosis and Health Association deals with the incidence, significance and course of infection of tuberculosis in racial and other groups and its relation to exposure. The facts upon which the report is based were collected from the records of infants brought to the baby health stations and clinics of the association and to city hospitals. The report states that among 4,003 infants under 2 years of age in two hospitals and clinics in New York City, the incidence of tuberculous infection was 11.4 per cent. Several among these had advanced tuberculosis. Among 1,656 infants of the same age, in attendance at baby health stations where the

majority were in good health, and in clinics, among whom none had manifest tuberculosis the incidence of infection was only 3 per cent.

Troubles We Don't Talk About—
By J. F. Montague, M. D., F. A. C. S.,
(Ill.) Philadelphia: Lippincott, 1927.
248 pp. Price, \$2.00.

The dedication of this book describes it as well as any lengthy review could do: "These pages are dedicated to those who suffer in silence, linger in doubt and carry on in despair, so that they, too, may enjoy better health and longer life." It deals with what are generally considered minor ailments, concerning which a physician is not consulted.

We will add that the object as announced has been well carried out, and it is seldom that a reviewer has submitted to him a book which is so interesting and for which there is so little room for criticism.

We would like to call special attention to what is said about the advertisements of the producers of various sorts of foods, and the concluding statement: "Thus the billboards have become the menu card of our nation."

The book might be more fully illustrated with advantage, though such illustrations as it contains convey their meaning clearly. It is well printed on light paper with a mat surface.

M. P. RAVENEL

BOOKS RECEIVED

PARENTHOOD AND THE CHARACTER TRAINING OF CHILDREN. By Thomas Walton Galloway, Ph. D., New York: Abingdon Press, 1927. 224 pp. Price, \$1.00.

CONVALESCENCE, HISTORICAL AND PRACTICAL. By John Bryant. White Plain: Burke Foundation, 1927. 269 pp. Price \$5.00.

PULMONARY TUBERCULOSIS. (2d ed.). By David C. Muthu, M. D. New York: Wm. Wood, 1927. 381 pp. Price \$5.00.

PHYSICAL CHEMISTRY AND BIOPHYSICS FOR STUDENTS OF BIOLOGY AND MEDICINE. By Matthew Steel, Ph. D. New York: Wiley, 1928. 372 pp. Price, \$4.00.

THE RATE OF LIVING. By Raymond Pearl. New York: Knopf, 1928. 185 pp. Price, \$3.50.

TONIC HARDENING OF THE COLON. By T. Stacey Wilson. New York: Oxford, 1927. 210 pp. Price, \$2.50.

THE TEETH AND THE MOUTH. By Leroy L. Hartman. New York: Appleton, 1927. 93 pp. Price, \$1.50.

THE CHILD AND THE HOME. By B. Liber. New York: Vanguard Press, 1927. 248 pp. Price, \$.50.

THE ABILITIES OF MAN. THEIR NATURE AND MEASUREMENT. By C. Spearman. New York: Macmillan, 1927. 415 pp. Price \$4.50.

PETERSHAM'S HILL. By Grace Taber Hallock. New York: Dutton, 1927. Price, \$2.00.

THAT MIND OF YOURS. By Daniel B. Leary. Philadelphia: Lippincott, 1927. 226 pp. Price, \$1.75.

THE CURRENT SIGNIFICANCE OF THE WORD "ALUM." By William D. Richardson. Chicago: Commonwealth Press, 1927. 93 pp. Price, \$1.00.

AMERICAN RED CROSS TEXT BOOK ON FOOD AND NUTRITION. A STUDY OF THE BASIS OF FOOD SELECTION. By Ruth Wheeler in collaboration with Helen Wheeler. Philadelphia: Blakiston, 1927. 123 pp. Price, \$.60. (paper cover)

SOURCES OF INFORMATION ON PLAY AND RECREATION (rev. ed.). By Marguerita P. Williams. New York: Russell Sage Foundation, 1927. 94 pp. Price, \$1.00.

OCCUPATIONAL GROUPS AND CHILD DEVELOPMENT. By Stuart M. Stoke. Cambridge: Harvard University Press, 1927. 92 pp. Price, \$1.00.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Philadelphia, Pa.—Accomplishments of the Philadelphia Department of Public Health from 1924 to the middle of the year 1927 are reviewed in a special issue of the monthly bulletin for November. This report is characterized by interesting text summaries of the health and hospital bureaus and by the use of good photographic and statistical illustrations of activities and results. The entire publication consists of 32 pages, size $11\frac{3}{4} \times 9$ inches, printed in good type in relation to the length of line and kind of paper used.

A threatened smallpox outbreak in the spring of 1926 stimulated general vaccination, at which time about one-half million people were thus protected. An intensive diphtheria immunization campaign was undertaken in 1924, since which time 255,604 persons have been immunized (192,555 in public and parochial schools and 63,049 in clinics, day nurseries, etc.). In the contagious disease hospital, a suction apparatus used in the treatment of patients ill of laryngeal diphtheria, seems to have given favorable results. The use of scarlet fever antitoxin has become more extensive than previously with apparently lowered death rates resulting. Convalescent measles serum, and parental whole blood have been utilized to prevent outbreaks of measles, especially in hospital populations.

School nurses during the year secured the correction of 139,750 of the physical defects (over 50 per cent of those recommended for treatment) found in pupils by school medical inspectors. Infant mortality is the lowest in the history of the city and has been cut in half during the last 15 years. Each year there is

observed a Public Health Day when health talks are delivered by prominent speakers before various clubs; exercises are conducted in schools; radio talks are given, etc. These campaigns emphasize the importance of periodic health examinations, the prevention of diphtheria, and the early diagnosis of cancer.

The report describes the organization of the medical emergency corps of Philadelphia to meet any medical emergency which may arise in or about the city. Interesting and detailed accounts of the various hospitals, including the hospital for mental diseases, conclude this record of progress.

U. S. Army—The Surgeon General's report for the fiscal year ending June 30, 1927, contains much information of interest to public health workers as well as to those directly connected with Army affairs. It is a report which abounds in carefully prepared text tables (171) and graphic figures (50). Tabular headings are complete but concise, while headings and sub-headings are effectively used in the text. A carefully prepared table of contents at the front and an alphabetical index at the back facilitate a study of this report of 501 pages.

The mean annual strength of the total Army for the year, exclusive of nurses, was 132,377. The admission rate to the sick report from all causes, and from diseases, was highest for the white troops in the Philippine Islands. The second highest rate from all causes was for the Porto Ricans in Panama. The leading causes of admission for the total Army from diseases were bronchitis, influenza, tonsillitis, and gonorrhea; and the leading causes from external causes were in-

juries resulting from athletic exercises, falls, animals (non poisonous), and automobile accidents. An annual death rate of 3.94 per 1,000 was recorded, as compared with 3.77 in 1925. The advance in the death rate from diseases was due to an epidemic of respiratory diseases during the first 4 months of the year. The leading causes of death in order of magnitude were: suicide (44), pneumonia, all forms (41), drowning (36), and tuberculosis (33).

In his letter of transmission, the Surgeon General emphasizes the need for increased personnel. "A Medical Department capable in time of peace only of rendering attendance for the sick and wounded, to the entire exclusion of major national defense objectives, is certainly not desirable. Such a contingency is probable in the near future unless more personnel is authorized."

Forsyth Dental Infirmary—The 12th annual report of the Forsyth Dental Infirmary for children contains the following significant paragraph: "In the effort to secure the prevention of tooth defects, all sources and kinds of treatment are being utilized as indicated, including ultra-violet irradiations, cod liver oil, dietary changes and stimulation in function of the endocrine glands as an aid in improving calcium metabolism. This is of course in addition to the already well established practice of early dental treatment which has given such satisfactory proof of its efficiency."

In addition to important research studies, and work with children (up to age 16), the dental prenatal clinic developed in coöperation with the Community Health Association of Boston assists in conserving the mother's teeth and in developing good teeth for the child. Children from families financially unable to obtain the service of a private dentist come to the infirmary through the public and parochial schools, social centers, institutions, physicians and dentists, and

are also brought by their parents. In 1926, 182 certificates were awarded to classes with "all dental work completed."

White Plains, N. Y.—An excellent report for a city of 28,707 people is that of White Plains. The report is printed on soft paper, in type easily read, and includes as features: a detailed appraisal, two good photographs of the department building and offices, and several charts and graphs. The lower half of the title page contains a graphic representation of the appraisal of the various functions of the department. The second page gives the department organization, while pages 3 and 4 contain a table of contents. The total score, on the basis of 1,000 points, of health practice in this city is 827. A per capita expenditure by the health department of \$.85 compares with one of \$.80 by the nursing associations, \$.56 by the Board of Education for Health, and \$1.22 by the Department of Charities for communicable disease and psychopathic cases.

During 1926, 71 per cent of the babies were born in hospitals. A birth rate of 24.6, a death rate of 11.3, and an infant mortality rate of 50 are reported.

Lowell, Mass.—The 49th annual report of the Lowell Board of Health for 1926 is bound in soft blue covers with a well arranged front cover. Introductory pages show the organization of the board and department, the expenditures for the year, and most important vital statistics. On the basis of an estimated population of 112,759, a death rate of 13.7 was recorded. An infant mortality rate of 89.6 compares with one of 83 for the previous year. Figures for the past 33 years, from 1893 up to and including 1926, "make apparent an infant mortality rate in which the number of deaths has been lessened 66 2/3 per cent."

The milk inspector's report is one of the most interesting features because of

the detailed analysis of activities and results. The per capita daily consumption amounted to 0.7 pint, 68 per cent being pasteurized. There were 81 dealers, 20 operating pasteurizing plants.

New Hampshire—The biennial report of New Hampshire for the period ending June 30, 1926, indicates increased scope of activities and greater demands for service. "The educational work which the department has carried on for years through bulletins, lectures, etc., is fast bearing fruit." Considerable effort has been directed to the safeguarding of water supplies, with favorable results. A birth rate of 20.79 and a death rate of 14.51 for the year 1925 are recorded. Four new laws enacted at the 1925 session of the legislature included: (1) bottler's licensing and registration law, (2) juvenile camp licensing law, (3) household chemicals law, and (4) law regulating the composition of embalming fluids. An account of inspection procedures of juvenile summer camps, with a list of summer camps in the state, showing address, attendance, and water supply, is one of the features of this 254 page report.

Philadelphia Schools—School health administrators will find in the 1926 report of the Division of Medical Inspection of Philadelphia (Pa.) Public Schools many interesting records of activities and results. A photograph on the title page of a school body, 97 per cent immunized against diphtheria, is at once suggestive of the preventive campaign being waged. In all, 122,000 pupils were immunized in 4 months. The personnel for the entire school health program consisted of 1 director, 12 supervisors, 97 medical inspectors, 1 head nurse, 95 nurses, and 7 clerical assistants. There were 229,054 pupils in elementary schools, with 28,678 in senior high, normal and trade schools, and 10,160 in

continuation schools. The yearly cost per pupil (not including continuation schools) of the service was \$1.16.

Routine physical examinations numbered 241,146, with 72,447 pupils being classed as physically normal. There were 270,564 defects recommended for treatment, 51.5 per cent of which were corrected during the year. The data concerning these problems are analyzed in considerable detail. Nurses made 37,709 visits to schools and 9,870 visits to pupils' homes. Nutrition and nutrition-tuberculous classes are of the open window type; in the latter group there are approximately 125 children who suffer from incipient but definite tuberculosis.

This division furnishes necessary medical service for the Bureau of Compulsory Education in connection with the issuance of employment certificates to children between the ages of 14 and 16 years. Approximately 31,183 examinations were made, and 4,126 children were refused certificates at the time of their first application. Over half of these children later secured the correction of disqualifying defects and obtained certificates. In several hundred cases there was restriction against employment of the child among power driven machinery, because of imperfect eyesight, imperfect hearing, or other good reason.

Worcester, Mass.—Graphic analyses of tuberculosis cases reported annually by wards, for 5 years, with effective representation of attendance at clinics, feature Worcester's 1926 report. During the summer, 207 children attended Sterling Health Camp, where 103 were given X-Ray examinations in addition to the routine physical. On the basis of a population of 190,757, a birth rate of 22.5 and a death rate of 14.17 are recorded. It is noteworthy that a record of the principal communicable diseases for the year is maintained by wards of the city.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Vaccination and Tetanus—Epidemiological evidence is presented which indicates that post-vaccination tetanus, when it develops, tends to follow severe primary vaccinations performed with large insertions and dressed with some type of shield or covering strapped to the site. An important contribution with which all health workers should be familiar.

ARMSTRONG, C. Tetanus Following Vaccination Against Smallpox and Its Prevention. *Pub. Health Rep.*, 42:50 (Dec. 16), 1927.

Maternal Mortality—The growth of prenatal clinics in America and the steps under way to increase the value of this service is summarized. The goal is to make this country not the most unsafe, but the safest for women during the period of childbirth.

BAKER, S. J. Maternal Mortality in the United States. *J. A. M. A.*, 89:24 (Dec. 10), 1927.

Goiter and Scholarship—Data are presented to show that students with normal thyroids more frequently attain high scholastic standing than do goitrous persons.

BEARD, J. H. Endemic Goiter and Scholastic Standing. *Nation's Health*, 1:12 (Dec.), 1927.

British and American Longevity—The expectation of life of males was about the same in both America and Great Britain in 1921 (being 55.5+); whereas, for women the expectation was 59.5 in England 57.7 in the United States.

BRITAIN, R. H. Expectation of Life in England and in the United States. *Pub. Health Rep.*, 42:48 (Dec. 8), 1927.

Measles Epidemiology—An interesting paper emphasizing the importance of nursing and hygiene in preventing

measles mortality, and the predictability of measles outbreaks. Rational preventive measures are outlined and urged.

GODFREY, E. S. Epidemiology of Measles. *Nation's Health*, 9:12 (Dec.), 1927.

Cannery Supervision—A symposium by British health authorities on the supervision of meat, fish, fruit, and vegetable packing, and the sanitary inspection of canned products.

GRANT, R., et al. Canned Meat-Preparation and Inspection, etc. *J. Roy. San. Inst.*, 47:6 (Dec.), 1927.

Antirachitic Factor in Milk—Cow's milk produced under ideal conditions contains negligible amounts of the antirachitic factor—even human milk does not protect against rickets. A technical dissertation concluding that fish oils, egg yolk, and liver are the most available sources.

HESS, A. F., and WEINSTOCK, M. A Study of the Antirachitic Factor in Human Milk and in Cow's Milk. *J. Dis. Child.*, 34:5 (Nov.), 1927.

Vaccine Virus As An Antigen—Studies confirming the statement that animals may be immunized by injections of killed vaccine virus, and passively immunized by immune serum.

HUNT, L. W., and FALK, I. S. Some experiments on the Antigenic Properties, Filterability and Microscopy of Vaccine Virus. *J. Immunol.*, 14:6 (Dec.), 1927.

University Student Health—An address on the health influence of colleges, covering student health conservation, education regarding individual and community health, the training of sanitarians, and the promotion of research.

KERR, J. W. The University in Relation to the Public Health. *Pub. Health Rep.*, 42:47 (Nov. 25), 1927.

Heredity and Rheumatism—An attempt to marshal the evidence in favor of the hereditary influences of rheumatic fever. Interesting mental gymnastics, the practical value of which is none too apparent, for the author does not suggest the remedies if his contention were true.

JONES, A. B. The Hereditary Factor in Acute Rheumatism. *J. State Med.*, 35:12 (Dec.), 1927.

European Supervision of Midwifery—The saving of maternal and infant life through rationally supervised midwifery in Europe is offered as an example of what might be done in those states of our own enlightened country which do nothing to improve conditions among their midwives. Another story to jar our complacency.

KOSMAK, G. W. Results of Supervised Midwife Practice in Certain European Countries. *J. A. M. A.*, 89:24 (Dec. 10), 1927.

Teaching Hygiene—A description of the methods used in teaching practical hygiene in the Newton (Mass.) schools. The children suggest health topics, choose their order of presentation and develop courses with little aid from their teachers.

LATIMER, I., and SIMON, C. Teaching Hygiene to Grammar and High School Pupils. *Nation's Health*, 9:12 (Dec.), 1927.

Needs of County Health Units—Adequately trained health officers and subordinate officials are the most pressing needs in the extension of the county health unit program.

LAUGHINGHOUSE, C. O'H. County Health Work. *J. A. M. A.*, 89:26 (Dec. 24), 1927.

Milk Consumption—An average per capita milk consumption of 0.48 quarts in Massachusetts during 1923 indicates that the ordinary estimates of milk consumption are too high.

McFALL, R. J. Per Capita Milk Consumption in Massachusetts. *Nation's Health*, 9:12 (Dec.), 1927.

British Milk Supervision—This illuminating account of the formalities and red tape demanded by British law when grossly contaminated milk is received will cause American sanitarians to thank their lucky stars that more direct and effectual powers are granted by our health laws.

LLOYD, J. S. Tuberculous Infection in Milk as Affected by Recent Legislation. *J. Roy. San. Inst.*, 47:6 (Dec.), 1927.

"Normal" Growth and Diet—Records are presented to indicate that rats may be made to grow at a greater rate than that regarded as "normal," and that the "curve of repair" scarcely surpasses the true normal growth upon appropriate diet.

MENDEL, L. B., and CANNON, H. C. The Relation of the Rate of Growth to Diet. *J. Biol. Chem.*, 75:3 (Dec.), 1927.

Dietary Deficiencies—Studies are presented which lead to the conclusion that foodstuffs carrying vitamins A and B contain other growth promoting substances than the generally accepted water-and fat-soluble groups, without which optimum growth is not attained.

PALMER, L. S., and KENNEDY, C. The Fundamental Food Requirements for the Growth of the Rat. *J. Biol. Chem.*, 75:3 (Dec.), 1927.

Infant Diets—An interesting diet table for children of from 6-13 months is presented. It provides, first, the fats, then the roughage and vitamins needed to establish correct alimentary functions.

PRITCHARD, E. Preventive Treatment of Digestive Troubles in Young Children. *Lancet*, 2:26 (Dec. 24), 1927.

Streptococci Causing Abortion—A pleomorphic streptococcus recovered from the tonsils and placenta of a woman having repeated abortions produced abortion or uterine hemorrhage in rabbits. The study corroborates the theory that focal infections of streptococci may give rise to spontaneous abortion.

REITH, A. F. Streptococci As a Cause of

Spontaneous Abortion. *J. Infect. Dis.*, 41:6 (Dec.), 1927.

Scarlet and Diphtheria Mixed Infections—Of 100 diphtheria patients, 29 gave cultures of hemolytic streptococci from nose or throat. Of these, 16 were shown to be scarlatinal. It is possible that some were scarlet fever cases in diphtheria carriers. Results indicate the advisability of individual isolation.

RHOADS, PAUL F. The Incidence of Scarlet Fever Streptococci in Throats of Diphtheria Patients. *J. Infect. Dis.*, 41:5 (Nov.), 1927.

A City Cardiac Survey—Of the 120,000 school children in Boston, 2311 heart cases were picked up in the routine school child examinations. The majority (1,344) were found to have no significant disease; 265 were classed as doubtful, requiring reexaminations; the remainder required special treatment.

ROBEY, W. H. A Cardiac Survey of Children in Boston Public Schools. *Nation's Health*, 9:12 (Dec.), 1927.

Exercise for Cardiacs—A paper emphasizing the importance of supervised, graduated exercise after recovery from heart infections; assuming that the attack has come to a close only when the temperature has not risen above 99.60° F. for ten consecutive days.

ST. LAWRENCE, WILLIAM. The Problem of Exercise for Children with Heart Disease. *J. A. M. A.*, 89:27 (Dec. 31), 1927.

School Sanitary Survey by Laymen—The Kentucky Rotary was called in to conduct a survey of the rural schools. An inspection blank was furnished and instructions printed. A fol-

low-up to improve the insanitary conditions found is now in progress.

THOMAS, A. A. Kentucky Rural School Survey on Health and Sanitation. *Nation's Health*, 9:12 (Dec.), 1927.

Antirachitic Effect of Sunshine—A series of important papers measuring the antirachitic effect of direct sunlight at various seasons; the effect of skyshine (indirect sunlight); and sun's rays through the special window glasses. Too inclusive for summarization here.

TISDAL, F. F., and BROWN, A. Seasonal Variation of Effect of Sunshine (and other papers). *J. Dis. Child.*, 34:5 (Nov.), 1927.

Endemic Goiter Prophylaxis—The endemic goiter occurring in an urban district in England in which there is little possibility of iodine deficiency cannot be attributed to that cause. Iodine prophylaxis hence cannot be recommended. The author suggests vitamin deficiency as a possible cause, and emphasizes the spontaneous recovery in many cases.

TURTON, P. H. J. Prophylaxis and Treatment of Childhood Goiter. *Lancet*, 2:23 (Dec. 3), 1927.

Undigested Proteins—That a proportion of the protein intake may be absorbed undigested under certain conditions has long been a commonly accepted fact. Here is offered immunologic evidence to prove it. Of interest to health officials dealing with anaphylactic and dietary problems.

WALZER, M. Studies in Absorption of Undigested Proteins in Human Beings. *J. Immunol.*, 14:3 (Sept.), 1927.

NEWS FROM THE FIELD

WARNING AGAINST VACCINATION SHIELDS

FROM the U. S. Public Health Service again comes the warning against the use of any sort of shield or dressing applied to a vaccination spot. It is emphasized that shields or dressings applied to a vaccination often are a cause of severe "takes" and delay healing.

DR. STREETER AWARDED KIWANIS MEDAL

HOWARD R. Streeter, M.D., Fellow A. P. H. A., Health Officer of Manchester, N. H., was recently awarded the Kiwanis Medal for distinguished service to the Community of Manchester. The Kiwanis Medal is given annually to the person or organization that has rendered the greatest service to the community during the year. A marked decrease in contagious disease since 1921 when Dr. Streeter became Health Officer of Manchester was cited among his several public health achievements.

HEALTH SERVICE OFFERED BY CONNECTICUT STATE DEPARTMENT OF HEALTH

THE Connecticut State Department of Health, Bureau of Public Health Instruction, offers a service of films, slides, posters, and health leaflets dealing with several public health topics. The pamphlet *Health Service* lists 42 motion picture films with a brief description of each film. A list of health slides and posters available is also included. This pamphlet is one of the most valuable for the health worker's reference shelf of aids in health education.

A GOVERNOR SPEAKS FOR PUBLIC HEALTH

THE value of public health work was emphasized by Governor Alfred E. Smith of New York in his annual message to the State Legislature. Governor Smith pointed out some of the achieve-

ments of the public health program in the past 10 years and emphatically stated:

Proper attention to the preservation of the public health will produce a strong, healthy, vigorous people. There is no greater state asset.

Governor Smith surveyed the development of the state's public health activities, including the state and local laboratory service, state aid to rural communities, public health education and supervision of water supplies in several municipalities, and supervision of oyster beds on Long Island.

He referred to the amendments to the Medical Practice Act of 1926, the maternal and infant health program carried out, and the school health and nursing programs. He said:

It must be borne in mind that for thoroughly effective health work, the state must have the full cooperation of the localities. The counties should do their share. The state stands ready to give financial and other aid, but unless there is a live, local interest in the public health problem, the desired progress is difficult to make.

TRAILING A FAKE EYE SURGEON

HEALTH authorities throughout New York State are on the trail of a fake eye surgeon, one Simon Mohr, who has been extracting large sums for his services. For his operations he has selected villages and rural communities. The publicity given to his practices attracted considerable attention. One of the last reports made to the New York State Department of Health is that he rendered services in a family in North Rose, Wayne Co., but only charged \$400, a fee much smaller than he had demanded some weeks previous in Orange County.

Commissioner of Health, Dr. Matthias Nicoll, Jr., put the Superintendent of State Police on the search for "Dr."

Mohr, and a warrant for his arrest has been sworn out.

CHICAGO CITY COUNCIL COMMENDS DR. BUNDESEN

AT the regular meeting of the City Council of Chicago, Wednesday, December 14, a resolution was presented expressing appreciation of the services of Herman N. Bundesen, M.D., former Commissioner of Health of Chicago.

It was unanimously voted that the resolution become a part of the public record of the Council proceedings, and that a copy be suitably engrossed and presented to Dr. Bundesen as a token of the esteem and affection in which he was held by the Council members.

The outstanding achievements of Dr. Bundesen's 6 years' administration are cited. He is credited with markedly improving the health of the community through the efficient management of the health department, through new methods of health education, the promulgation of sound policies and rulings, establishment of higher standards of living, advancement of sanitation and more intensive disease control.

The resolution also pointed out that the death rate dropped from 13.71 per 1,000 population during the previous 7 years to an average rate of 11.5 per 1,000, "establishing thereby an unequalled record among all large cities of the nation."

Dr. Bundesen's fight for a pure milk supply, his campaign for the education of mothers in the care and feeding of infants, the establishment of infant welfare stations, and distribution of special health publications—all of which aided in reducing the death rate of Chicago babies under 1 year of age from 89.3 per 1,000 births in 1921 to 63.8 per 1,000 births in 1927—were recorded in the appreciation of his services.

The resolution stated that Dr. Bundesen had developed a department of

health whose efficiency has attracted and stimulated the interest in programs of other cities, and one of the greatest recognitions of his ability was his election to the presidency of the American Public Health Association. The Council commended him as an example and inspiration to "health officials the world over."

It concluded:

Resolved, that we, the members of the City Council of the City of Chicago, do hereby convey to Dr. Herman N. Bundesen our personal and official appreciation and that of the people of the City of Chicago for the great and valued service the benefit of which no one can overestimate, and that we hereby express the hope that in life's pursuits he will find even greater opportunity to devote his ability and experience to the interest of health, happiness and public well being.

DIPHTHERIA IN MANCHESTER, N. H.

THE first mention of diphtheria in the health department reports was in 1885 when 18 deaths were recorded. The following year, 1886, 9 deaths from the disease were reported; in 1887, 73 cases and 17 deaths were recorded. Since 1887, diphtheria has been reported regularly, and both number of cases and rate have been high, in fact, above the general average of cities of like size. The total number of cases of diphtheria and number of deaths have exceeded the cases and deaths from scarlet fever. The highest number of cases reported in any year was 492 in 1908 and in the same year the highest number of deaths, 41, was recorded; the lowest number of cases was recorded in 1899—but in that same year 9 deaths were recorded and, thus, the number of cases reported is manifestly wrong; the lowest number of deaths, 1, was recorded in 1893. The disease has always increased in incidence soon after schools opened in the fall; the ages of greatest incidence have been 6 and 7; four-fifths of the cases have occurred under 15 years of age. November 1, 1921, control measures,

comprising Schick testing, toxin-antitoxin treatment, antitoxin immunization of immediate contacts, culturing for carriers, quarantining carriers until cured, were instituted. The results were immediate and striking. The incidence both in morbidity and mortality has declined from 469 cases with 31 deaths in 1921, to 9 cases with 2 deaths in 1927. The diagnosis of 1 fatal case in 1927 was in doubt but the cause of death was given as diphtheria and was so recorded.

More than half the school population has been immunized or is Schick negative.

The following table gives the incidence for the past 7 years:

Year	DIPHTHERIA		
	Rate per 100,000		
	Cases	Pop.	Deaths
1921	469	585	31
1922	254	317	27
1923	188	230	15
1924	81	99	6
1925	31	37	6
1926	12	14	3
1927	9	10	2

NATIONAL COST OF BLINDNESS

THERE are 100,000 blind persons in this country. The preventable causes of blindness have cost this country more than \$100,000,000 in the last 10 years, according to a statement given out by the National Society for the Prevention of Blindness. It is not costing more than \$100,000 a year to carry on the work of preventing blindness and conserving vision generally in the United States. Industrial accidents alone cost the industries of the country nearly \$10,000,000 every year and are responsible for 15 per cent of our blind population.

The society is directing its efforts against all causes of blindness including ophthalmia neonatorum, trachoma, venereal diseases, industrial eye hazards and accident hazards in public and home life.

FUND TO FIGHT COMMON COLD

A 5-year war against the common cold will be directed by Johns Hopkins University and the Johns Hopkins Hospital, and financed by the Chemical Foundation of New York. A fund of \$195,000 to be known as "The John J. Abel Fund for Research on the Common Cold" has been established with a promise that more funds will be raised if needed to continue the research. The research will be conducted on a coöperative basis involving the staff and facilities of every department in the Medical School, the School of Hygiene and Public Health and the University Hospital.

Dr. Abel is professor of pharmacology at Johns Hopkins University, and conducted the researches that led to the discovery and synthetic production of adrenalin. He was the first to isolate the pure chemical principle of insulin.

GOITER SURVEY IN TENNESSEE

A SURVEY of goiter incidence will be made in Tennessee beginning April 2 under the direction of Dr. Robert Oleson of the U. S. Public Health Service. Dr. Oleson is one of the leading authorities on goiter.

School examinations by the Division of Child Hygiene in different parts of the state have shown a considerable variation of incidence of goiter in different sections. Tennessee hopes to determine by Dr. Oleson's survey if it has a goiter problem of sufficient extent and importance to require additional attention of public health officials.

RURAL HEALTH DEMONSTRATION CONTINUED

TO raise the health standards of rural communities and reduce mortality rates throughout the country as the result of its public health experiment in Cattaraugus County, N. Y., directors of the Milbank Memorial Fund have appro-

appropriated \$87,000 for the continuance of the demonstration program in Cattaraugus County. The demonstration program was originally planned for 5 years. This additional appropriation will provide for another year of work. The total grant for the demonstration program has been \$500,000. The Cattaraugus County Governing Board has within the 5-year period appropriated \$113,000 and the State of New York has contributed appropriations totalling \$95,000.

The demonstration is being continued at the specific request of Cattaraugus County health authorities, despite the opposition from a small group in the local medical society.

The conspicuous achievements in Cattaraugus County during the 5-year demonstration period has been a reduction of about one-third in the tuberculosis death rate, and nearly one-fifth in the infant mortality rate. More than 50 per cent of the 150,380 physical defects of the rural school children found by medical examiners have been corrected. Approximately 50 per cent of the children of the county under the age of 10 have been immunized against diphtheria. There has also been a marked reduction in bovine tuberculosis as a result of the program carried out by the demonstration directors in coöperation with specialists and federal and state officials.

DR. PLATT APPOINTED TO NEW POSITION

PHILIP S. Platt, Ph.D., Secretary of the Associated Out-Patient Clinics Committee, New York Tuberculosis and Health Association, has been appointed Assistant Director of that association. Dr. Platt will continue as Secretary of the A. O. P. C., and will also have direct supervision of the Committee on Community Dental Service and the Tuberculosis Committee of the association.

Dr. Platt is a Fellow of the A. P. H. A. and is Chairman of the Public Health Education Section of this Association.

CALIFORNIA

SIR ARTHUR Newsholme, M.D., K.C.B., former chief medical officer of the Local Governing Board of England and Wales, who is spending the winter at Santa Barbara, Calif., was guest of honor at a banquet given by the Southern California Public Health Association at Los Angeles, January 13. About 200 members and their guests were present.

Sir Arthur was introduced by Dr. J. L. Pomeroy, President of the Association. Sir Godfrey Fisher, British Consul, extended the welcome. Sir Arthur spoke briefly, touching upon constructive public health policies.

Sir Arthur Newsholme was instrumental in the forming of the British Ministry of Health, correlating all public health functions under one department and eliminating the confusion arising from many different bureaus acting for the government. He was lecturer on public health administration at the school of Hygiene and Public Health, Johns Hopkins University, Baltimore, Md., 1917-1919.

MASSACHUSETTS

THE 1928 annual meeting of the Massachusetts Association of Boards of Health was held in Boston, January 26, at Hotel Bellevue.

The responsibility for the care and treatment of tuberculosis by the Commonwealth and by the town, city and county with the attendant difficulties of settlement, subsidy, and responsibility is a subject of much concern to those entrusted with this work, besides being confusing as to charges and cost. Therefore three aspects of the problem of tuberculosis were presented at this meeting:

"Present Resources for Handling Tuberculosis in Massachusetts," George H. Bigelow, M.D., Commissioner of Public Health of Massachusetts

"Local Care and Responsibility of Tuberculosis," George T. O'Donnell, M.D., Director,

Division of Tuberculosis, Boston Health Department

"Settlement Laws and their Application to Tuberculosis," William H. Hardy, formerly secretary, Department of Public Welfare, City of Boston

The 1927 officers were reelected, namely: President—John J. McGrath, Salem; 1st Vice-Pres.—M. Victor Safford, M.D., Boston; 2nd Vice-Pres.—J. U. Paquin, M.D., New Bedford; Secretary—Stephen L. Maloney, Boston; and Treasurer—F. G. Curtis, M.D., Newton.

Executive Committee: George R. Lennon, Haverhill; Lyman A. Jones, M.D., Norfolk; E. H. Trowbridge, M.D., Worcester; J. H. Glennon, M.D., New Bedford; and Jacob R. Sackett, Springfield.

MICHIGAN

OVER 300 sanitarians attended the seventh annual public health conference conducted by the Michigan Public Health Association, an Affiliated Society of the A. P. H. A. and the Michigan Department of Health. This meeting, held at Lansing, January 11, 12 and 13, 1928 was better attended than any of the six preceding ones.

The officers of the Michigan Public Health Association elected for 1928 are: President, John Sundwall, M. D., University of Michigan; Vice-President, Prof. Ellis J. Walker, Western State Teachers College; Secretary-Treasurer, W. J. V. Deacon, M. D., Bureau of Records, State Dept. of Health, Lansing, Mich.; Representative to the A. P. H. A., Guy L. Kiefer, M. D., State Health Commissioner, Lansing, Mich.

Board: T. W. Worley, Michigan Tuberculosis Association; Grace Ross, R. N., Dir. Nursing Division, Dept. of Health, Detroit, Mich.; R. C. Mahoney, Chairman, Public Health Committee, Michigan State Medical Society; Don Griswold, M. D., Deputy Health Commissioner, Michigan State Board of Health; and William G. Stapleton, M. D., Wayne Co. Medical Society.

SOUTHERN CALIFORNIA

THE Pomona Health Center, erected by Los Angeles County at a cost of \$68,000 on property given by the city of Pomona, recently opened its doors for

service to the public. The new building said to be one of the best equipped health centers in the country has been erected adjacent to the other municipal buildings in the civic center. Every phase of public health service will be housed in this building.

The health center was opened with a formal program attended by Los Angeles County and Pomona city and health officials and representatives of the medical profession.

J. L. Pomeroy, M. D., county health officer and head of the department under which the center functions, visited the health centers of several eastern cities, and is convinced that in the Pomona institution has been incorporated the most extensive public health service of any centers visited.

The Pomona Health Center is the third of such institutions being built by the Los Angeles County Health Department. Health centers are also to be erected at Santa Monica and Belvedere.

TENNESSEE

S. S. Moody, M.D., formerly Health Officer of Weakley County, has accepted the position of Health Officer of Washington County in East Tennessee. Dr. M. D. Ingram, of Gibson County has been recommended to fill the vacancy as Health Officer Weakley County, which is left vacant by Dr. Moody.

Wilson County will have a full-time health department. This is the result of a unanimous vote of the Wilson County Medical Society. Tennessee now has 17 full-time health departments, with 3 counties in addition that have the county sanitary officer plan of work.

VIRGINIA

AT the annual meeting of the Virginia Public Health Association, an affiliated Society of the A. P. H. A., at Suffolk, Va., January 4-5 the following officers were elected: President, C. P. Ransom, M. D.; Vice President, C. H. Dorsum; Secretary-Treasurer and A. P. H. A. Representative, P. S. Schenck, M. D.

PERSONALS

William F. Wild, M.D., has been appointed Health Officer of Bridgeport, Conn., assuming his duties February 1. Dr. Wild resigned his position with the Division of Public Relations of the American Child Health Association to accept the Bridgeport appoint. He was formerly field representative for the American Society for the Control of Cancer, executive secretary of the Minnesota Public Health Association at St. Paul, and also served as director of laboratories and epidemiologist and later health commissioner of the State of Nebraska. Dr. Wild received his medical training at the Tulane Medical School, Tulane, La., and his public health training at Harvard University and the Massachusetts Institute of Technology.

Bernard S. Coleman has been appointed executive secretary of the Hudson County Tuberculosis League, Jersey City, N. J.

George Bevier, M.D., formerly field director of International Health Board, New York, N. Y., is now at Bogota, Columbia, S. A.

W. W. DeBerard, formerly chief engineer of the Chicago Regional and Planning Association is now associate editor of the *Engineering News-Record*, with headquarters in Chicago.

William L. Holt, M.D., formerly of Portland, Me., has become affiliated with the Medical Department of the Ciba Co., pharmaceutical branch, with headquarters in New York, N. Y.

Charles C. Evans, formerly teacher of physiology and Hygiene at Stevens Point, Wis., is at Chicago University doing research work in public health.

Dr. Ethel R. Harrington has been ap-

pointed to the staff of the Division of Child Hygiene and Public Health Nursing of the Illinois State Health Department.

Dr. A. W. Haskell, Associate Milk Specialist of the U. S. Public Health Service has been detailed for one year to the Tennessee State Health Department. Dr. Haskell will conduct field investigations in milk control work throughout the state, coöperating with the Tennessee State Health Department.

W. D. Riley, Regional Consultant for the U. S. Public Health Service, has been assigned to the Tennessee State Health Department for a study of venereal disease prevalence in the state.

Harry Bruce Wilson, superintendent of schools, Berkeley, Calif., has been appointed National Director of the American Junior Red Cross. Mr. Wilson will assume his duties February 1. He succeeds the late Arthur W. Dunn who was director of the organization for six years.

Felix M. Massey, Dean of Men, University of Tennessee, Knoxville, Tenn., has been appointed as a specialist in the Land-Grant College Survey being conducted by the U. S. Bureau of Education. Dean Massey's duties will include the preparation of a questionnaire dealing, among other things, with the health services for students and their regulations, and the housing and feeding of students in the colleges.

Edward Bausch, president of the Bausch and Lomb Optical Co., Rochester, N. Y., has been elected an honorary member of the American Microscopical Society "in recognition of more than 50 years of active interest in microscopy."

Dr. Thaddeus P. Hyatt has been ap-

pointed Supervising Dentist of the New York City Department of Health. His services are lent by the Metropolitan Life Insurance Co., where he is director of dental education, to supervise the extension of the department's work among school children which now has a staff of 19 dentists and 25 dental hygienists.

Ira V. Hiscock, Assistant Professor of Public Health, School of Medicine, Yale University, Fellow, A. P. H. A., has been appointed a member of the Board of Health of New Haven, Conn., for 5 years, beginning February 1. The appointment was made by Mayor John B. Tower of New Haven.

Charles E. Miner, formerly executive secretary of the Missouri Social Hygiene Association, St. Louis, Mo., has gone to Chicago to become Superintendent of the Committee of Fifteen. The purpose of the committee is "to aid the public authorities in the enforcement of laws against pandering and to take measures calculated to prevent traffic in women."

Mrs. Frances W. Everberg of Woburn, Mass., has been appointed chairman of the Woburn Municipal Board of Health. Mrs. Everberg is a graduate of the Massachusetts General Hospital Training School for Nurses and during the war served with the Massachusetts General Hospital Unit No. 6.

Dr. Warren E. Danley has been appointed health officer of Union City, Mich. to succeed Dr. Ernest E. Hancock.

Dr. Henry L. Burdeno has been appointed health officer of Dearborn, Mich.

Gerald Wendt, Ph.D., dean of the school of chemistry and physics, and director of the division of industrial research, Pennsylvania State College has resigned, effective in July, to become director of the Battelle Memorial Institute for scientific and industrial research, Columbus, O., which has recently been founded.

Dr. Henry Hanson has been appointed field officer for the Florida State Board of Health with headquarters at DeFuniak Springs. For several years Dr. Hanson has been engaged in the study of yellow fever in Africa.

Dr. Herman N. Bundesen has been appointed Health Director of the Chicago Sanitary District and also Health Editor of the *Chicago Daily News*.

Beginning January 1, 1928, Dr. J. C. Geiger was granted leave of absence for one year by Dr. Kegel, the new Health Commissioner of Chicago.

Dr. I. S. Falk has announced his resignation as Director of Surveys and Exhibits of the Chicago Health Department.

Arthur E. Gorman, in charge of the safety of Chicago's water supply with the Division of Engineering, has been suspended by request of the Health Commissioner. Mr. Gorman has been appointed Epidemiologist of the Chicago Sanitary District.

Medico-Legal Aspects of Occupational Disease*

HENRY H. KESSLER, M.D.

Medical Director, New Jersey Rehabilitation Commission, Newark, N. J.

and

BERNARD S. COLEMAN,

Industrial Secretary, New Jersey Tuberculosis League, Newark, N. J.

WHEN the compensation laws of the various states were first enacted, occupational diseases were given no place. The benefits were confined to industrial accidents and their sequelae. Though the word "accident" was interpreted strictly in the beginning, this interpretation was soon given a liberal construction and the word "accident" was in many cases changed to "injury" to facilitate the inclusion of conditions obviously not accidental. Infections such as anthrax, typhoid fever, acute cases of poisoning such as lead and metal fume fever thus became compensable before the definite inclusion of occupational disease in the compensation acts.

The same consideration that prompted the move for compensation for industrial accidents—the severe economic and social distress of injured workers—prompted the gradual inclusion of occupational diseases into this scheme of relief. It seemed only fair and just that industry take the burden from the shoulders of the worker who was engaged in employment that was sure to shorten his life and expose him to hazards that would disable him physically and economically.

This necessity for allowing compensation in cases of occupational disease has been recognized by several of the states, so that at the present time the federal government and 12 states, including Hawaii and Porto Rico, include occupational diseases in their compensation

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

laws. This inclusion is accomplished in three ways: by the word "injury" denoting accident and occupational disease; by the court's interpretation of the word accident; and by the enumeration of a specific list of occupational diseases. Minnesota, New Jersey, New York, North Dakota, Ohio and Porto Rico all have special lists, the diseases to be compensated for being specifically stated. Some of the states not only specify the disease, but also the restricted processes in which it must be acquired in order to be compensated.

With the inclusion of occupational disease in the compensation laws of these states, compensation boards and commissions now have the added problems of arbitration and administration of awards for occupational affections. The arbitration of such awards may be easy or difficult, depending on the wording of the act as well as its scope. Where the act specifies a list of 10 diseases, as in New Jersey, the work is more or less simplified. Where the whole gamut of human illness is thrown open to an occupational etiology, as in California and Connecticut, the difficulty of adjudication becomes great. It would seem more practical and equitable to accord pecuniary benefits in the latter case through a system of workmen's sickness insurance.

New Jersey in 1924 amended its compensation act to include occupational disease. It now has 10 such diseases listed:

- | | |
|---------------|------------------------------------|
| 1. Anthrax | 6. Chrome |
| 2. Arsenic | 7. Wood alcohol |
| 3. Lead | 8. Benzene and its homologues |
| 4. Mercury | 9. Caisson disease |
| 5. Phosphorus | 10. Mesothorium or radium necrosis |

This constitutes 1 infection (anthrax), 1 affection due to compressed air (caisson disease) and 8 poisons. Prior to the inclusion of the list, anthrax had already been construed as compensable while many of the poisons were compensated for their effects in cases of sudden exposure due to accidental leaks in piping or unavoidable accidents in technical processes. New Jersey does not prescribe the process in which the disease must be contracted, thus liberalizing the construction of the act considerably.

Those who appreciated the important rôle played by the compensation law for accidents in the increased reporting of accidents felt a justifiable expectation in the increased reporting of occupational disease. This, fortunately, has been realized. It is our impression after eight years of service that three times as many claims for occupational disease have been filed since its inclusion. However, the number of cases reported is still insufficient. This lack of increased reporting can be explained: First, the law is only three years old; second, occupational

disease is for the most part insidious and does not make the strong impression that accidents do; third, the medical profession is still far behind in the detection or appreciation of occupation as an etiological factor in the causation of disease.

Occupational disease in New Jersey is reportable to the State Board of Health by the doctor in a similar manner to the reporting of communicable disease. There is, however, no special form, nor is reporting compulsory. The State Department of Labor receives a copy of each report submitted and upon its receipt makes a complete investigation. Occupational disease is reportable also to the State Department of Labor by the employer on the same blanks as accidents are reported. Every claim for compensation in occupational disease is investigated by the factory inspectors of the Department of Labor.

In Ohio where excellent work has been done in the matter of legislation for the proper reporting of occupational disease, more than 4,500 cases of occupational disease of all types were reported between the years 1921 and 1925. Yet, this number is far below the actual incidence of occupational conditions.

Dr. Wade Wright found 2,000 occupational disorders out of 32,000 patients in the out-patient department of the Massachusetts General Hospital, an incidence of 6 per cent, of which in one year 148 cases of lead poisoning were found.

The improvement of occupational disease reporting depends on the combination and coöperation of several agencies: First, the compulsory reporting by physicians on special forms to the state department of health; second, the compulsory reporting of employers to the state department of labor; and third, the establishment of an occupational disease clinic under state auspices for the actual demonstration of the examination of workers and the detection of occupational disease conditions, as well as serving as a clearing house for information to the physician, employer and employe. Such a clinic has been proposed in New Jersey, and the first will be opened at Newark.

In the three years since occupational diseases have been compensated for in New Jersey, 1210 claims have been filed, of which 420 have been held non-compensable. Of the 790 compensable claims, 265 were for lead poisoning, 110 for benzol poisoning, 114 for mercury poisoning and 241 were for occupational dermatoses. The rest were scattered among the remaining compensable diseases with the exception of phosphorus poisoning, no such case being filed for claim.

The responsibility for the arbitration of awards of compensation for occupational disease rests for the most part upon the medical adviser. The referee and commissioner look to him for a correct and

intelligent solution of the various problems they must meet. They need answers to the following questions:

1. Is this man suffering from a compensable illness?
2. Was it acquired or aggravated at the last place of employment?
3. Does he require further treatment, or, is he able to work?
4. Has he suffered any permanent vital changes which will affect his future earning and working capacity?
5. If he dies—was the death the result of a specific occupational disease?

The task of the arbitrator or medical examiner is therefore fivefold.

He must do the following:

1. Make a diagnosis
2. Determine the responsibility for the occupational disease if it exists
3. Decide the temporary period of disability
4. Determine the permanent disability
5. Determine the cause of death

DIAGNOSIS

Our first problem is that of differential diagnosis. For example, in lead poisoning the symptoms must be differentiated from those of other affections. We must distinguish lead colic from the gastric crises of tabes and syphilis, lead encephalopathy from epidemic encephalitis, lead arthritis from other infectious arthritides and lead anemia from the anemia of malignancy.

Where these symptoms stand alone without other clinical or laboratory support, the diagnosis is uncertain. Colic occurring in a worker exposed to lead is not considered compensable unless accompanied by other objective clinical findings such as radial extensor weakness, lead line or by laboratory evidence of basophilic degeneration of red blood cells. In this respect, the use of the Martin spring balance to detect minor reductions in the strength of the radial extensors has been found very helpful. Such a finding is considered sufficient corroboration to justify a diagnosis of compensable lead poisoning. The question of differentiating between lead absorption and lead intoxication does not ordinarily concern us since most of the claimants appear because of some subjective or objective symptom related to intoxication. However, the detection of lead poisoning in workers without symptoms, but with definite lead line or laboratory evidence of the disease, such as may be disclosed at the periodical examination which is compulsory under our law for lead workers, automatically entitles them to the benefits of compensation. The following cases are illustrative of the problem of diagnosis:

A claimant aged 65 had worked in a lead smelter for 15 years and had been exposed to lead fumes and dust. His chief complaint was a constant tremor of both hands and a slight incoordination in walking. On examination, he disclosed

a typical syndrome of Parkinson's disease with masklike facies and tremor of hands and legs, propulsive gait, monotonous speech and loss of associated movements. His blood showed no changes except for a Hb of 80 per cent and a red cell count of 4,400,000. His claim was disallowed.

A negro aged 32 had worked for 2 years in the grinding room of a paint factory when he ceased to work on account of severe cramp-like abdominal pain. He alleged lead poisoning and filed a claim for compensation. He was found to have no other clinical or laboratory evidence of lead poisoning but he did have a positive Wassermann. His symptoms cleared up rapidly under mixed treatment. No compensation was allowed.

Workers on lead storage batteries are aware of the lead hazard and often file claims without any definite clinical symptom or complaint except for occasional malaise or giddiness. It is surprising to find marked stippling and a severe anemia present in these cases without more clinical symptoms. Examination of the urine and feces however reveals large excretion which explains the mildness of their symptoms.

A paster in a lead storage battery plant had worked at his last place of employment for 8 months and had been free from symptoms. He was seized one day with cramps and placed himself under treatment by a physician. He filed a claim for compensation and was examined. His blood was apparently normal, Hb 90 per cent, red count 5,200,000. His only symptom was colic. His urine showed definite lead excretion. He was allowed compensation. In many cases the evidence may be only presumptive, but the benefit of the doubt must be given the worker.

We have established three postulates each case should satisfy in order to meet the medico-legal test of compensable occupational disease:

1. The patient must demonstrate an exposure to the occupational poison.
2. He must demonstrate absorption of the poison by clinical or laboratory signs.
3. He must demonstrate clinical evidence of disability from this poison.

RESPONSIBILITY OF EMPLOYER

Having made our diagnosis, our next problem is that of determining the responsibility of the last employer. It would seem that this is essentially a problem for the referee or the commissioner, but the medical examiner is depended upon for the technical and medical information in most cases upon which the determination is based. New Jersey has no provision requiring the employe to have been employed in his last place of employment for at least a year before he can collect compensation for an occupational disease. Neither does it require the compensation to be divided up among the employers for the 12 months preceding the onset of the illness. The last employer generally pays for the entire condition unless he can conclusively show that the symptoms or signs, such as a musculo-spiral palsy, were

present at the time of hiring. An examination of 260 men for employment in a smelter disclosed at the time of hiring 32 men suffering from lead poisoning, as demonstrated by stippling in the blood picture. Twenty of these 32 denied ever having worked in lead.

Our chief problem occurs in those cases of chronic poisoning with no visible symptoms at the time of hiring who develop symptoms in their new place of employment. The questions we have to answer are: Is this a fresh case of poisoning? Is it an old one aggravated by his new employment? Is it an old case exacerbated by conditions outside of his employment, such as unhygienic living at home, dissipation or injury? These questions can only be answered intelligently when a complete analysis is made of each individual case. A thorough physical and biochemical examination, full information concerning his previous places of employment, as much as can be determined or ascertained concerning his outside mode of living and, finally, what the sanitary and hygienic conditions at the plant are.

One man had worked for a smelter for 18 years and was laid off at the age of 62. He had a double wrist drop which he admitted having had for 14 years, with which he was able, however, to continue at his work. Since this condition was acquired before the passage of the law, no compensation was allowed.

TEMPORARY DISABILITY OR PERMANENT DISABILITY

The temporary disability period is that period during which the sick worker is incapacitated from work on account of his illness. It is the task of the medical examiner to determine when that period should end, if it appears that the man is malingering; or to decide if he requires further treatment and abstinence from work if he is sent back to work too early. If he returns to work of his own accord, temporary disability is automatically terminated. For us to decide when a person is able to return to work is very difficult because of human variability and because of the many social and economic factors not related to illness. The determination must be based on objective findings of a specific nature, either clinical or biochemical. For example, in benzol poisoning a normal blood picture, normal weight and no other objective signs of illness, despite subjective complaints, should warrant the cessation of temporary disability.

Temporary disability terminates:

1. When all symptoms disappear
2. When the man returns to work
3. When symptoms are no longer confirmed by other objective findings

Compensation laws recognize the necessity for reimbursing the injured worker not only for wages lost during the period of his disablement, but also for the permanent effect of severe injuries and their end

results, such as amputations, ankylosis of major joints and paralyses, on the future earning capacity of the worker. Though no standards exist that might be used as a basis for measuring this permanent effect or disability, one of us has suggested in another communication the use of diminished physiological function of injured members as a basis for estimating the reduction in earning or industrial efficiency.

In a similar way, the slow insidious and cumulative effect of industrial poisons bears heavily upon vital organs and results in a definite measure of impairment of working efficiency, if not life expectancy. The medical examiner is charged with the responsibility of determining this measure of impairment in percentages of 100 per cent working efficiency and, upon the estimation submitted, compensation is awarded. For example, 100 per cent total permanent incapacity represents 500 weeks at the maximum rate of \$17 a week, or \$8,500. The permanent changes brought by lead poisoning, on the brain and cranial nerves in encephalopathy cases, on the kidney, blood forming organs, vascular organs or muscular system, must be translated into mathematical terms denoting impaired efficiency and earning capacity. The practice in the past has been for the attending physician representing the sick worker and the carrier's physician to submit estimates of disability based on their best judgment. The estimates submitted were always based on frank guessing with no indication of any basis for them; they were biased for the side they represented, and hence worthless.

We have proposed some basic principle that can be uniformly used that would not be arbitrary, yet would represent in some measure an approach to the requirement of a percentage estimation. The principles recognize first the importance of setting a time when the estimate or appraisal of permanent disability should be made. This period has been called by French writers the "period of consolidation." This period when applied to accidental injuries, is the time when the injury has healed sufficiently to enable the injured worker to return to work without any danger, or where the condition being so severe that he is unable to return to work, the pathological condition has shown no change over a specified period of time. Applied to occupational affections, estimating permanent disability at the time the injured worker returns to work is as a rule too early. The insidious and cumulative effect of industrial poisons takes a long time to indicate their ultimate immutable changes. We should say, therefore, that it is the period when the pathological signs have shown no appreciable change for a period of 4 to 6 months. This would bring this period in cases of lead poisoning to about a year or more after the last onset of the disease and

in mercury poisoning to 2 years and more after the last recognition of the presence of the disease.

Now, how shall we appraise the resultant damage caused by the specific occupational poisons? Let us see first what their effects are. The gross effects of these occupational affections make themselves felt in two ways: on the immediate or intermediate reduction in the strength or complete muscular power of the individual, and on the ultimate life expectancy.

The impairment of muscular strength is the result of direct and indirect action of the poisoning. Through its direct action on the peripheral nerve or neuromuscular mechanism, paresis or paralysis may develop, and through its direct action on the muscle, weakness also occurs. Through its effect on vital organs such as the vascular and renal organs, there is an indirect reduction in the general muscular strength. How can we measure this strength or loss of strength?

Strength may be measured ergographically or through the use of dynamometers. The ergographic method lends itself to much error since it depends for its findings on the fatigue factor, a thing that cannot be measured. Most dynamometers such as the common grip dynamometers give such variable results that they are worthless for any system of accurate measurement and, furthermore, depend on the voluntary control of the patient.

The Martin spring balance and method is an efficient method for determining muscular strength. The pull of eight muscle groups is registered in pounds on the spring balance and the result when multiplied by the factor 6.67 gives an accurate index of the total body strength. The test is simple to make and can be done by trained laymen. The result may be compared to some standard figures for the age, weight and height of the affected workman. These figures are not at hand in large numbers, although we have the results of 340 cases of varying ages, weights and heights. However, it is feasible to compare the strength to the job strength; that is, the minimum strength of workers employed at the same process. For example, if the job strength of color mixers is 2,800 pounds and the muscular total strength of the sick worker, 2100 pounds, there is a reduction of 25 per cent of his normal industrial efficiency.

The Martin strength test has had practical trial, in the investigation of poliomyelitis, soldier's heart, and estimation of job strength. We have used it in the determination of permanent disability of the accidentally injured for the past six years. This test is therefore practical and indicates the possibility of determining approximately the incapacity of workers from occupational poisoning or other affections.

It is a common feeling that the industrial hazards to which workmen are exposed are a definite factor in the reduction of their life expectancy, but there are no data that definitely state what this reduction is. Such data as exist, the mortality statistics by occupation, are not necessarily conclusive. They are by industries rather than by occupations and lump together a large number of widely varying employments. Although no statistics are available, it would seem rational and equitable to all concerned to compensate sick and injured workers on the basis of the reduction of their life expectancy. For instance, we know that the life expectancy for a man with one kidney removed is reduced 25 per cent. This is used as a basis for compensating those who have suffered the loss of one kidney through accident. If sufficient data could be gathered and tabulated to form a basis of such an appraisal, they could be used and checked up later by actual experience. For the present, the only statistics available show a death rate due to lead poisoning of 1 per cent for all cases, while for painters, chronic lead poisoning is given as a cause of death in only 2 per cent of every 11 cases. These figures of course are not significant for many reasons, among which is the fact that cerebral hemorrhage, apoplexy, paralysis, organic heart disease and kidney disease, all of which may be the end result of lead poisoning, are not considered as causes of death due to lead poisoning. Dublin estimates the diminished life expectancy of industrial workers as 8 years compared to non-industrial workers.

DETERMINATION OF THE CAUSE OF DEATH

Finally, it is the obligation of the medical examiner to determine the cause of death in disputed cases of death alleged to be due to occupational disease. As in the case of determining the responsibility of the employer, so in these cases is it necessary to analyze all the data in the case, which should include all medical and laboratory reports that would help to establish a diagnosis of occupational poisoning, the working conditions at his last place of employment, and at other places of employment, the history of previous attacks, and finally and most important, an autopsy. The cause of death of six girls employed in painting luminous dials on watches was undetermined and puzzling. Guesses of phosphorus poisoning, osteomyelitis of the jaw, and Vincent's angina were all made until the autopsy revealed changes throughout the entire hematopoietic system, indicating the use of a radium-like substance in its action, viz. mesothorium.

An experience with the management and adjudication of cases of occupational diseases leads us to the belief that only occupational poisons should be compensated; that all other forms of illness which

can directly or indirectly be traced to industrial conditions should be compensated through a system of workmen's sickness insurance; that increased reporting of occupational disease could be accomplished from a three-point attack: compulsory reporting of the doctor to the board of health, compulsory reporting to the department of labor by the employer, and the establishment of an occupational disease clinic, under state auspices, for the dissemination of information and the demonstration of methods of examination and detection of occupational disease.

The payment of compensation for occupational disease must be made in accordance with medical facts. Compensation for permanent disability should be based on accepted standards, not necessarily arbitrary, such as could be adopted or proposed by such an organization as the American Public Health Association. The use of the strength diminution and reduction in life expectancy is suggested as a rational basis for such an appraisal. Finally, the autopsy is an important factor in determining the cause of death.

DISCUSSION

Volney S. Cheney, M.D., thought that the time was at hand for the establishment of a Standards Committee for questions in the field of both industrial accidents and diseases.

C.-E. A. Winslow, Dr.P.H., said that the Crampton test should not be taken as a measure of general vitality, but it was of value in determining the response of the blood vessels. The Massachusetts occupational disease compensation law had been unsatisfactory. The law was not specific, as in those states which have schedules, so that compensation had been allowed for tuberculosis, heart disease, etc., where industry was very questionably at fault. As a consequence it had been difficult for employes with these and other afflictions to get work. However, last year the law had been changed limiting its application to specific occupational diseases. What was wanted in states where compensation laws exist is a qualified referee or bureau to act impartially upon the cases presented.

Frank G. Pedley, M.D., asked what was the source of so much mercury poisoning in New Jersey, also what was done with carbon monoxide poisoning. He would also like to hear more about the Martin spring balance in its industrial application.

Wade Wright, M.D., said that the broad coverage law in Massachusetts was too easy and that workmen's sickness insurance is the fairest thing. He felt sure that 4 of the lost years compiled by Dublin for industrial workers had not been considered as due to specific occupational disease, like poisons, etc., but to the general hazards of industry. He felt that one year was too short a time for estimating the ultimate damages produced by lead poisoning.

Otto P. Geier, M.D., asked Dr. Wright what length of time he would consider satisfactory.

George H. Wood, M.D., saw little point in waiting for an autopsy for a diagnosis. Were the three points mentioned for diagnosing lead poisoning, that is (1) proof of exposure, (2) signs of absorption, and (3) evidence of clinical disability, legal in New Jersey or just a personal construction?

Frederick L. Hoffman, LL.D., stated that the estimation of life expectancy is a very difficult proposition. It is necessary to work out life tables both with and without tuberculosis, heart disease, etc., in order to draw worth while conclusions. He commented at length upon the experience of life insurance companies in relation to disability clauses. He was much perturbed by the confusion of lead poisoning with lead absorption and his studies had shown that many cases of the latter were confused with lead poisoning. In addition to the reports already published upon mesothorium in New Jersey there were 5 exposed girls who had developed an almost identical hip affliction and were now hobbling around. It was a sad state of affairs when compensation had been allowed in only 1 of the 6 cases which had died and in only 1 case of sickness of 5. The state seemed helpless and the company was heartless. There are probably two or three more girls yet to be heard from. These cases demonstrate that a time for fixing permanent injury would not be safe under 6 years.

He felt that the broad Massachusetts law, in spite of what had been said, was better than any specific list. Silicosis was more important in this country than lead poisoning. Most cases required an exposure of from 18 to 21 years and practically none occurred under 5 years' exposure. Tuberculosis is superinduced by silicosis, but it was silicosis and not tuberculosis that should be considered in

compensation. The mortality in the Barre, Vt., district from silicosis with tuberculosis is appalling, and many workers suffer.

Emery R. Hayhurst, M.D., stated that occupational disease clinics in connection with medical schools in industrial centers have been a failure in his experience in two different cities. The finding of lead in the urine was only a sign of absorption and not in itself one of lead poisoning. Compensation without actual disability, as the foregoing paper implied, was a new idea. In Ohio, where a state monopoly insurance exists, "the last employer" does not enter into the compensation question. The industries are classified into some 700 groups, and the premiums are fixed for each group every 6 months depending upon the experience of the previous 6 months. In order to create a specific bureau for factory hygiene and sanitation 1 per cent of all premiums collected had been set aside. The occupational disease compensation fund was raised by charging 1 cent for each \$100 payroll. Up to two years ago the occupational disease premiums were varied according to the assumed risks in different industries ranging from a fraction of a cent to as high as \$4.00 per \$100 payroll, but the bookkeeping was so complicated that this method was discontinued. Now all industries pay the same premium for occupational diseases—1 cent per \$100 of payroll. Hence the inducement for a particular plant to allay its disease hazards is not present, but there is some inducement in that each industrial group is interested in lowering its premium rates. Dr. Hayhurst would consider that Dr. Kessler ought to deduct 4 more years after taking off the "industrial 8" mentioned by Dublin, for occupations having specific health risks such as lead poisoning, etc.

W. E. Obetz, M.D., stated that compensation in Ohio is based upon one's inability to work and may be partially apportioned accordingly. "We encourage the reporting of the minor phases of occupational diseases so that they may appear early and disability be stopped before anything permanent occurs. Today we seldom see compensation looking to standard practices."

Dr. Winslow said that after what has just been stated, the great advantage of the general state fund, as in Ohio, can be seen since the previous employment is of no particular interest. Here we have the state bureau vs. the paid expert. Twelve states now have compensation for occupational diseases. He moved that the Industrial Hygiene Section create a committee on "problems of occupational disease compensation looking to standard practices."

This motion, seconded by Bernard S. Coleman, was unanimously carried.

Dr. Kessler, at this point, said that at present industrial commissions were often paying out money in hit and miss fashion. They think they are proceeding in a satisfactory manner but in reality they do not know.

The use of the Martin spring balance test is important because the strength factor is a significant index of the worker's working capacity. For instance, in cases of lead poisoning there is often marked weakness which can be detected by the Martin test. To the same extent the Crampton index is valuable for noting the difference in vasomotor tone.

Whenever industry is a contributing factor it should promote a relief system rather than a damage system.

The cases of mercury poisoning in New Jersey come from batteries and from thermometer works principally. There were 24 cases of mercury poisoning during the past year.

"We regard carbon monoxide poisoning as an accident. Other acute chemical

mishaps are compensated for as accidents. Such was the custom before occupational diseases were included in our compensation schedule."

He said he had used the Martin test in 1340 cases in practice but only in a few occupational disease cases thus far. It is valuable for the measurement of job strength. For instance when tried upon 32 men in the same occupation (machine work) an average finding of 3200 lbs. was obtained. One of these men however suffering from chronic mercury poisoning gave a rating of 2600 lbs. a reduction of approximately 20 per cent in his physical strength.

"We find that occupational disease compensation amounts to only about 1 per cent of accident compensation. We all know that more occupational diseases exist than are compensated.

"The matter of whether we should deduct 4 or 8 or 12 years from the average life expectancy for the industrial worker is difficult to decide. Take the case of the removal of a kidney—how shall we compensate him? We have compensated such an individual to the extent of 25 per cent permanent disability based on his decreased life expectancy.

"There is, of course, a great question as to when we should fix the time limit before permanent disability is estimated. In neuroses, before deciding the case as one of permanent disabling character, we wait 1 year. If there has been no change in the last 6 months of this period the permanent disability is determined at the end of that 6 month period. In mercury poisoning we wait 2 years before deciding the permanent disability. The autopsy is used only when the case of death is one of dispute.

"The coöperation of the attending physician is necessary. His certificate must be backed up by corroborative evidence. Some 90 per cent of claims which come before the Commission are treated by the family physician."

In answer to Dr. Wood, he stated that the three postulates used for determining lead poisoning are not laid down in the statutes but are a valuable guide.

He said he had a mesothorium case at present, a woman who 7 years after exposure to luminous paint fell and hurt her shoulder; she now has pathology in the joint.

"Our proposed occupational disease clinic will work under state auspices. Only a small proportion of our occupational disease cases have permanent disability. A large percentage of our mercury cases however show permanent disability."

He hoped that the committee, which had been asked for, in the motion made by Dr. Winslow, would be a stimulus to other states to adopt compensation for occupational diseases.

Physical Education

THE Ministry of Hygiene and Physical Education of Czechoslovakia recently granted a subsidy of 4½ million crowns to private organizations for the promotion of physical education and in addition appropriated nearly 2 million crowns for the construction of public gymnasiums and athletic fields. The Ministry has also organized various courses on physical education for school and kindergarten teachers.—*Difesa Sociale*, Rome, Nov., 1927, p. 33.

The Technic of Meetings*

ARTHUR E. GORMAN, FELLOW A. P. H. A.

Former Chief Sanitary Engineer, City of Chicago, Ill.

AS a matter of simple courtesy, if for nothing else, it is incumbent on any organization to so "set the stage" for the presentation of technical papers or addresses at its sessions that the speakers may perform effectively, and the audience receive the fullest benefit from the presentations made, free from petty annoyances so common at public meetings of this type. Although the writer is of the opinion that in their organization and conduct the meetings of this Association compare favorably with those of others, there is still room for improvement and, therefore, offers this paper as constructive criticism of the meetings attended in the last six years.

It is, of course, assumed that the papers scheduled for meetings are on timely and worth while subjects; that they have been well prepared; and further that adequate announcement of their subjects and the place and time of presentation have been duly made in the convention program. There then remain three outstanding factors which must be blended to give a degree of harmony approaching the ideal conditions sought:

1. The selection, identification and arrangement of the meeting room
2. The conduct of the meetings by the officers
3. The speaker and his stage setting

Of prime importance is the advance selection of the meeting room. Its size will, of course, depend upon the estimated attendance, an item which will be gauged by the character of the session scheduled. The meeting room should be reasonably convenient to the convention headquarters or registration desk and yet sufficiently isolated that noises from within and without the hotel may not be objectionable. While meeting rooms on upper stories have the advantage of relative quiet from exterior noises, the congestion of elevators before and after sessions, when the attendance is large, should be considered as a contributory disadvantage. In a hotel located in a business district where outside noises are noticeable, inside meeting rooms are preferable provided efficient ventilation control is available. The degree and

* Read at a Joint Session of the Health Officers and Public Health Education Sections of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

probability of occurrences of various types of common noises should be carefully considered with the hotel officials in advance of selection of rooms.

Some of the exterior noises which must be considered in connection with outside rooms are those caused by trucking in streets and alleys; sand-blasting of adjacent buildings; automobile horns; street cars; elevated trains; boat whistles; news boys; traffic officers' whistles, etc. Interior noises which should be guarded against are those caused by ventilators; elevator machinery, and careless handling of silverware and dishes in adjacent rooms being prepared for private dining purposes. Unless the possibility of these noises affecting meetings is investigated in advance of the selection of the meeting room and provided against they are likely to occur under conditions which cannot be controlled and thus seriously interfere with an otherwise well organized meeting.

The meeting rooms should be easily located by those desiring to attend and to this end should be well identified. The printing in the official program of a floor plan of the hotel adjacent to the convention headquarters while helpful is not always noticed by those in attendance and to some is confusing. It is believed that beginning with the lobby in which registration is conducted there should be posted adequate signs with indicating arrows directing the delegates to the various meeting rooms. In addition, there should be set on an easel directly outside of the entrance to each meeting room, a sign giving notice of the section in session and the time of the opening of the meeting.

The layout of a selected meeting room will, of course, depend upon its size, proportions, and the estimated attendance. The writer is of the opinion that in general a room one and one-half times as long as wide is proportioned for making the most effective seating arrangement. (See Figure I).

The speakers' platform should be at the center of the wall on the long side of the room, most distant from the entrance. It should be elevated at least one foot and be approximately 7 feet deep, 12 feet across the front and properly carpeted. There should be an aisle of not less than 8 feet between the front of the speakers' platform and the first row of seats. Except in cases where seating capacity taxing the room accommodations is desired, it is believed that the three-block arrangement of seats is most satisfactory, as it concentrates the audience within reasonable hearing distance of the speaker. This calls for a center block of from 10 to 12 seats wide, with at least a 4-foot aisle on either side and right and left sectors or blocks. The seats should be set to form concentric rows, with the outside chairs on the end aisle of

FIGURE I—Sectional Elevation of Meeting Room

the wing sections making approximately a 30° angle with the wall behind the speakers' platform, and on a radial line from this point. Should this result in the rear rows being over 10 or 12 chairs wide, supplemental aisles should be left to facilitate easy access and exit to and from the seats. (See Figure II.)

In case additional seating capacity is needed the five-block system can be used, which is less satisfactory to those sitting in the extreme wings. There should be an aisle at least 6 feet wide at the rear and two sides of the meeting room. To avoid crowding, adjacent chairs in each row should be set 6 inches apart and the distance between the front and rear of chairs in consecutive rows should be at least 14 inches. In the ordinary set-up of chairs for convention purposes these distances are not usually provided for, with the result that those in attendance are crowded and cramped. This condition often develops restlessness which is reflected on the dignity of the meeting shortly after the session is in progress, continuing more or less intermittently throughout the session. The width of seating blocks should be limited to from 10 to 12 chairs, for the convenience of the audience in assembling and departing. Furthermore, persons leaving early or coming late would not then disturb the session seriously by passing out in front of a number of people.

In arranging the set-up of the meeting room special attention should be given to the entrances and exits. These should preferably be in the rear or on a side near the rear of the room. A most annoying condition at our meetings has been the noise of conversation in the lobby which is carried through the entrances and exits. For several reasons it is undesirable to entirely close the entrance and exit doors and under such circumstances the writer is of the opinion that a screen should be placed in front of each entrance. This will not only shut off

external noises but eliminate the distraction to those reading papers caused by the opening and closing of doors. As a further precaution it is believed that a sign reading "Meeting in Session, Please Observe Quiet" posted at the meeting room entrance would have a desirable effect.

On the elevated speakers' platform there should be a stand or table of convenient height at which the person holding the attention of the audience should stand, whether he be the chairman directing the meeting or a speaker. In large meeting rooms, such as those held by our general sessions, amplifiers for directing the speaker's voice to to all points of the hall have been much in need. The writer is of the opinion that the desk for the chairman, clerk and stenographer should be at the front of the room between the speakers' platform and the first row of seats. At the rear of the room near the entrance there should be a table for the monitor.

A most important item in the setting of a meeting room is the location of the screen for stereopticon or moving picture illustrations and the machines for rendering these services. It is common in meetings to locate the stereopticon machine in the center aisle, where it is not only in the way of the audience in arriving and departing, but also an obstruction to the vision of those in the room to the rear of the operator. Furthermore, it is a distraction to persons in the immediate vicinity of the machine due to the noise of the operation and the glare of side

FIGURE II—Plan View of Meeting Room

lighting when pictures are changed. The screen for stereopticon use should, in the writers' opinion, be either directly behind the speakers' platform or slightly to the right. It should be of such size that the bottom of the picture shown can be at least 1 foot over the head of the speaker, who should be equipped with a pointer sufficiently long to direct attention to any portion of the illustration shown on the screen. This will remove the speaker from the line of vision of a portion of the audience and at the same time eliminate the shadows caused by his head and arms in pointing to the illustration. The stereopticon machine should preferably be set up in the rear of the room, directed at right angles to the screen and sufficiently elevated either in a balcony or on a special platform so that the rays of light will not be interfered with by persons arriving and departing during the meeting and so that proper focus may be made at the elevation mentioned. The signal for change of slides should be silent, such as an electric light controlled by a button switch in the hand of the speaker, thus eliminating the cumbersome and noisy make-shift signals so common at our meetings.

For the last two or three years it has been the custom in the meetings of this Association to maintain a bulletin announcing the speaker at other sectional meetings during sessions. This is considered a good practice providing its operation does not distract the attention of the audience. At one of our meetings the messenger received and transmitted information of changes of speakers by telephone, which was very annoying. At another meeting the monitor in charge was unusually noisy in operating the bulletin. If such a bulletin is to be operated it should be of special construction, illuminated by shaded lights and set at least 10 feet to the left of the speakers' platform. Its design should be such that the name plates for speakers may be exchanged with very little annoyance. It would be well if the Association had such equipment for permanent use.

Decorative equipment, such as flags, shields, etc., should be so placed in room as not to interfere with the line of vision to the speaker and the screen, and should be firmly mounted in order that they may not distract attention during the meeting by falling from the walls or tipping over.

CONDUCT OF MEETING BY OFFICERS

Obviously, officers are necessary at meetings to expedite the business in accordance with standards of parliamentary practice and common courtesy. The time honored practice of having the presiding officer and clerk, and in some cases other officials, seated on the speakers' platform is subject to criticism from the standpoint of distracting attention from the speaker who should logically be the center

of interest to the audience. In the writer's opinion, except for business purposes, officers should be conspicuous by their absence. The chairman need only occupy the speakers' platform in opening and closing the meeting and announcing speakers, and at other times he should have the status of a listener. But this state of affairs can only be brought about where meeting plans are perfected in advance and where officers are properly trained in their duties. Too frequently conversation between the chairman or secretary of meetings and pages and others who enter the room distracts interest from the speaker. In some of our meetings the chairman has been little short of a petty nuisance to the speakers, with more dignity than common sense, and the effect of seating him at a table on a level with the other listeners would I believe be for the good of all concerned.

It goes without saying that the chairman should have a full knowledge of his duties and the courage to discharge them. He should have a personality which automatically establishes a dignified atmosphere throughout the session. His enunciation should be clear. He should insist upon punctuality in the opening and closing of the meetings as well as in the length of papers and discussions. It takes an efficient and courageous chairman to do this, but his efforts will generally be appreciated by everyone. A meeting scheduled for 9:00 o'clock should be opened promptly on that hour regardless of the attendance. The chairman should communicate with the speakers in advance of the meeting to be sure that they will be in attendance in accordance with the schedule and that their wants are cared for.

Changes in the order of the program should be discouraged, but if permitted should be announced at the opening of the session. At the opening of the meeting the chairman should request those in attendance who desire to leave the room to refrain from doing so while papers are being read. The writer is of the opinion that on request from the chairman for no smoking during the meeting there would be gracious compliance. Speakers should be requested to seat themselves in the front row reasonably convenient to the chairman's desk, where they may be interviewed, if necessary, with as little distraction as possible and from which place they may ascend to the speakers' platform without delay and inconvenience to the audience.

The secretary should be seated at the desk with the section chairman and automatically perform his duties with as little distraction to the audience as possible. He should, if practical, make arrangements in advance for the turning in of copies of papers read. When serving as chairman he should observe the same rules of conduct mentioned for that officer.

A most important ally of the officials at meetings and one rarely present at our sessions is a monitor. In a well conducted meeting the services of a monitor are extremely valuable if the officers are to be permitted to perform their duties effectively. There should be one on duty in every meeting room where sessions are in progress. Monitors could be enlisted from some of the Boy Scout troops or high school classes. The monitor should have a special desk at the rear of the room, preferably near the entrance. Prior to the opening of the meeting he should see that the layout of the room by the hotel employes is in accordance with the established schedule, special attention being given to such matters as the seating arrangement; the location of the chairman's and stenographer's desk; the speakers' platform and stand; the decorations; stereopticon screen and equipment; the bulletin; all lighting equipment for the meeting room; the ventilating apparatus; the adjustment of the windows and shades; the pointer and drinking water for the speaker. The monitor should receive either from the speakers personally or others charged with their custody the slides to be used in connection with illustrated papers, and should arrange to return them, properly packed, to the owner. He should also attend to the changes in the bulletin announcing speakers at other meetings and reciprocate relative to speakers in the room under his charge. He should receive all special messages during the meeting and quietly deliver them in written memoranda to the chairman. He should keep a record of the attendance, reporting to the secretary, and should periodically adjust the heating and ventilating equipment to provide proper atmospheric conditions within the meeting room. He should thoroughly understand the lighting system for the meeting room in order to make adjustments necessary when stereopticon service is used.

The stenographer for all meetings should be provided with desk space reasonably convenient to the section chairman so that speakers may be identified, and to receive proper instructions and information for effectively reporting the progress of the session. Stenotype operators should be properly instructed in their duties in advance of the meeting, taking orders there only from the section chairman.

THE SPEAKER AND HIS STAGE SETTING

In advance of meetings the speakers should announce their presence to the chairman and receive any last minute instructions. They should be seated in the front row convenient to the chairman and the speakers' platform, thus avoiding the embarrassment and delay which invariably develops when the presence of speakers is unknown or their location in the room such that when called upon they must disturb all present in the aisle in which they are seated.

All arrangements for turning in copies of reports and for stereopticon service should be made before the meeting opens. The passing out of samples, reprints, etc., by the speaker prior to or during his presentation should be discouraged. These should be given to the monitor for distribution before or after the meeting and the request for announcement of this procedure made to the chairman. If large demonstrations, such as models, maps or charts are to be used, the speaker should arrange with the monitor in advance of the meeting for their display.

If the speaker must first attend another meeting and arrive late this fact should be made known to the proper section chairman. After introduction by the chairman and proper acknowledgment by the chair the speaker should always mount the speakers' platform. The so-called reticence and reserve which some speakers display by not mounting the speakers' platform frequently makes it difficult for persons in distant sections of the room to see and hear them, and usually weakens the presentation considerably. During periods of discussion the speaker should retain his place on the stage. If stereopticon illustrations are used, and it is practical to do so, speakers should shorten the time of their presentation by having a second person point to the important features being illustrated while the paper is being presented. Frequently speakers read a paper and then practically double their allotment of time by repetition in demonstrating with stereopticon illustrations. The practice of breaking the presentation of papers by such demonstrations is a weakness in our programs which could be avoided if arrangements were made for assistance in advance.

In conclusion, I desire to say that by comparison the A. P. H. A. meetings are generally well conducted, their weaknesses being an inheritance of custom and lack of training by section officers, seasoned with an element of courtesy to the individual which gives way to the efficient organization of a well balanced machine. The keynote is mutual coöperation and team work, with the executive officers of the Association modestly directing the stage with dignity and discipline from behind the screen.

Relations Between Health Departments and Hospitals.*

THE relations which have grown up between hospitals and health departments in recent years have been discussed at several meetings of the American Public Health Association, more particularly since the Boston meeting in 1923 when considerable interest in the subject was shown.

In 1926 the Association together with the *Modern Hospital Magazine* collected some information regarding the extent and form of coöperation between hospitals, dispensaries, etc., and health departments in the fields of laboratory examinations, hospitalization of communicable diseases, and maintenance of public health clinics, in cities of 40,000 population and over. The information secured showed that a goodly number of hospitals had certain working relationships or agreements with municipal, county or state health departments.

The Association believed it would be helpful both to health officers and to hospitals, to have more information on the exact nature of this coöperation. The undersigned committee was appointed by the chairman of the Committee on Administrative Practice to make this inquiry. Three members were suggested informally by the president of the American Hospital Association, including the chairman of that organization's Committee on Public Health Relations.

A contribution of \$1,500 was secured from private sources to finance the work. The office of the American Public Health Association assumed responsibility for the collection, analysis and tabulation of facts.†

The committee met in February, 1927, and agreed upon a plan of study, and again in September to review the facts collected and to determine conclusions. This report was then presented in substance to the full Committee on Administrative Practice and accepted thereby.

The study embraced the character and extent of the working relationships between public health departments (municipal, county or state) in cities of 30,000 population and over with general, maternity,

* Report of a Study by the Committee on the Study of the Relations of Health Departments and Hospitals, a sub-committee of the Committee on Administrative Practice, presented to the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

† The committee appreciates the services of Anna C. Phillips, R.N., who made the necessary field visits.

and children's hospitals of 25 beds and more, and clinics and health centers unattached to hospitals in these cities. Hospitals directly under health department control were, of course, excluded.

The specific areas in which coöperation was studied were 3, namely, laboratories, hospitalization of communicable diseases and clinics. For the purposes of this inquiry, coöperative working relations were defined as follows:

Laboratory Service—Examinations made for a hospital by a health department or examinations made for a health department by a hospital, with or without payment for the work.

Hospitalization of Communicable Diseases—The care in non-departmental hospitals of scarlet fever, diphtheria, measles, whooping cough, tuberculosis, syphilis, gonorrhea or smallpox at the request of, or in coöperation with, a health department, whether paid for or not from public funds.

Maintenance of Clinics of Public Health Interest—Joint operation, or aid by health departments in personnel, supplies or funds to the operation by a hospital of clinics of generally recognized public health importance, i.e., prenatal, preschool, well baby (infant welfare), tuberculosis, venereal disease, dental hygiene, hookworm and malaria, and also of some clinics in which the public health responsibility may be considered debatable—eye (all cases), refraction only, ear, nose and throat, mental, child guidance, periodic health examination, orthopedic and trachoma.

A summary of the work done follows:

1. Letter and questionnaire to health officers in 247 cities representing 242 cities over and 5 cities under 30,000 population; supplemented by a follow-up letter to those not replying and a notice regarding the study in the Association's monthly news letter to health officers for June, 1927.

2. Letter and questionnaire to 1,365 general, maternity and children's hospitals in the 247 cities, including 28 dispensaries, health centers, etc., in 12 of the cities selected tentatively for field visit because of unusual situations disclosed by the information furnished.

The replies from hospitals were used to elucidate the situations reported upon by health officers. They also constitute the only source of information for those cities from which no official reply was received.

The percentages of responses to both inquiries, according to size of city are presented in Table I.

3. Correspondence with health officers to secure further information on the details of situations reported upon and to clarify replies which were not definite or which conflicted with the facts furnished by local hospitals.

4. Visits to cities in which unusual types of coöperation have developed to secure opinion regarding the advantages, desirability and details of operation.

The facts furnished cover about one-half of all the cities under 100,000 population and over 80 per cent of those of 100,000 and more.

The outstanding general impression from the study is that there have grown up a number of specific and evidently useful forms of coöperation between health departments, hospitals, and various voluntary agencies, and this coöperation has developed spontaneously and

* Based on the Federal Census of 1920

** Includes five cities under 30,000 population

without propaganda. The officials of the participating organizations in each community have acted on the basis of immediate local situations without much, if any, knowledge that similar undertakings are growing up elsewhere.

The main advantages of such coöperation in the opinion of those participating in such programs are: (1) Economy; (2) the ability to cover special fields to an extent not possible with the funds available directly for the health department; (3) better quality of service; (4) the possibility of reaching a wider audience through close contact with voluntary health organizations with their broad appeal; and, (5) the possibility of undertaking new services through pooling of resources, which could not be undertaken satisfactorily by one agency alone.

FINDINGS

The extent to which these various forms of coöperative relationships exist throughout the country is indicated by the number of cities reporting joint health work of this character, and the number of institutions (hospitals, dispensaries, health centers, and other voluntary health agencies and social agencies with health activities), involved in the information furnished. These facts are set forth in Table II, and commented upon in succeeding pages. The committee has had prepared a detailed summary of the types of coöperation found in each of the 148 cities reporting, and while this is too extensive to print, there are mimeographed copies in the office of the Association, available on request of any member.

* Exclusive of an unstated number of institutions in cities in which health department furnishes service to any hospital upon request

Types of Coöperation in Laboratory Service—A new point of interest, not anticipated when the study was planned, is the extent to which health departments purchase laboratory service from privately operated hospitals. In Schenectady, N. Y., the health department pays \$10,000 annually to a voluntary hospital for all the examinations, both for the department and for a municipally operated health center. In Dubuque, Ia., a private hospital supplies service to the health department for \$200 a month. In Muskegon, Mich., a voluntary hospital does examinations for diphtheria, tuberculosis and gonorrhea for the health department on the basis of a fixed charge for each item.

Two interesting variations are in McKeesport, Pa., where the city provides a pathologist and the salary of a technician to a hospital's laboratory which does all examinations for the health department except urine and pathological specimens; and in Harrisburg, Pa., where one of the hospitals occasionally makes examinations for tuberculosis, syphilis and gonorrhea; and also of urine, feces, fowl and meat from slaughter houses, pneumonia typing and tuberculosis cultures, the city furnishing a technician to the hospital to assist with this work.

The reverse form of coöperation, in which hospitals use the health department laboratory, is chiefly for:

1. Examinations for acute communicable diseases—diphtheria, typhoid, tuberculosis, syphilis or gonorrhea

2. Examinations of the more unusual conditions with which hospitals rarely deal—rabies, malaria and plague, chemical analysis of food and drugs, milk and water

3. Checking the work of their own laboratories, as in diphtheria and syphilis

State health department laboratories are used fairly extensively both by city health departments and public and private hospitals for examinations for syphilis, and appear to be the chief reliance in many

of the smaller communities in respect to examination of food and drugs, milk and water, and for rabies.

One of the interesting situations disclosed by the study is the extent to which the health departments in the larger cities furnish laboratory service to non-medical voluntary organizations, such as settlements, day nurseries, neighborhood houses, and other philanthropic agencies. These ordinarily do not maintain laboratories but frequently need certain routine examinations. Boston, Los Angeles, Chicago and San Francisco present instances of this type.

In comparatively few cities does the health department receive payment for work done for hospitals, dispensaries, etc. In some localities the county health department pays the municipal laboratory for county work done, as in Springfield, O., where the city is paid \$.50 for examinations for diphtheria, tuberculosis, gonorrhea, and of urine, and \$1 each for chemical analyses of food and drugs, milk and water.

The question naturally arises: What should be the municipal or state health department control of the standards of work in hospital laboratories diagnosing communicable diseases? Of the procedures in privately owned laboratories furnishing similar services to hospitals? The steps already taken by state health departments in this respect are illustrated by Decatur, Ala., where the laboratory used by the municipal health department is an official branch of the State Department of Health; and by Albany, N. Y., where the private laboratory used by the health department is officially endorsed by the State Department of Laboratories and Research.

Types of Coöperation in Hospitalization of Communicable Diseases—The utilization by health departments of private general hospitals for the care of acute communicable diseases is now recognized as a sound policy which holds advantages for both groups. For the health department these are chiefly: (1) economy in the cost of controlling communicable diseases; and (2) provision of better service.

The hospital derives advantage from the arrangement due to: (1) the broader service it can offer internes; (2) the student nurses being able to receive desirable experience in this special field at their own institution instead of being sent to other hospitals; and (3) payment from public funds for patients with communicable diseases who are unable to pay or are hospitalized against their will.

Typical of situations in which the payment for hospitalization comes from the health department is Newport, R. I., where a voluntary hospital cares for scarlet fever, diphtheria, syphilis and gonorrhea for \$3.50 a day, paid through the health department which exercises full control over admissions and discharges, a communicable disease hos-

pital being used only in extensive emergencies when the cases exceed the capacity of the contagious disease unit of the private institutions. In Pittsfield, Mass., a voluntary hospital receives all types of communicable diseases excepting tuberculosis and smallpox, the city providing an annual subsidy of \$5,500 for the maintenance of the service, plus \$21 per week per patient cared for, paid through the health department.

Among the cities in which care is furnished and payment made other than through the health department, is Camden, N. J., where two voluntary hospitals provide the city with service, one admitting scarlet fever, diphtheria, measles, syphilis, gonorrhea and smallpox, and the other, syphilis and gonorrhea only. No specific payment is made for the care furnished patients with communicable diseases as it is considered to be included in annual appropriations of \$25,000 made to each institution by the City Commissioner and the County Board of Freeholders.

Four voluntary hospitals in LaCrosse, Wis., receive syphilis and gonorrhea, one of them in addition receiving all other types of cases, for which the city appropriates \$1,200 annually to cover the cost of the care of indigents, the county paying for county charges and transients. Examples of payment by a per capita daily or weekly rate are: Chicopee, Mass., hospitalizing all cases except tuberculosis and smallpox in two private hospitals for from \$18 to \$21 per week; Jamestown, N. Y., hospitalizing all types of cases for \$4 a day; and Stamford, Conn., where \$14 a week is paid for town (indigent) cases of communicable disease, including smallpox.

Some dozen cities which report they do not maintain any municipal hospitals for communicable disease purchase service from nearby cities which have such hospitals. For example, Lakewood, O., buys such care from the Cleveland City Hospital, the department of health paying at the rate of \$5 per day; cases of communicable disease in New Britain, Conn., are cared for in Hartford, the Department of Charities carrying the responsibility of payment for those unable to pay.

An interesting point is the fact that coöperation between hospitals and health departments in this field is reported mainly from cities under 200,000 population, only 8 of the cities over 200,000 noting arrangements in this respect.

Not the least significant of the entrance of the private hospital into this public health field, is the number which receive smallpox—a situation which seems to presage the doom of the “pest house.”

The numerous and successful instances of coöperation in this field suggest their desirability and community value. In the development of such programs it should be recognized that in the hospitalization of

communicable disease, the responsibilities of the health department relate primarily to approval of quarters, equipment, etc., and to the admission and release of patients, but do not extend to administrative responsibility within the hospital.

The various methods of payment in effect indicate that reimbursement of privately operated hospitals on a per capita per diem basis is well established; also that per capita payment for the amount of care furnished plus an annual subsidy to cover hospital overhead is in successful operation. The last plan seems the fairest to the hospital.

Attention has been called to the fact that payment is often made from city or county funds, but not through the health department; also that appropriations from public funds sometimes cover a variety of hospital services, including the care of patients with communicable diseases, the amount available for this purpose not being separately listed.

In the interest of sound and uniform accounting for health work, methods of payment of public funds through other channels than the health department should be abandoned in favor of including all amounts expended for the control of communicable disease, including hospitals, in the health department's budget.

Types of Coöperation in Public Health Clinics—The field of public health clinics includes so many different kinds of service and touches so many agencies other than hospitals, it naturally presents a greater opportunity for coöperative effort than laboratory service or communicable disease care.

Coöperation between hospitals and health departments in this field in general consists of the furnishing by the hospital of quarters and equipment while the health department provides some or all of the medical, dental, nursing, social service or clerical personnel. The individual situations vary from complete control of the clinic by the hospital, with the health department merely coöperating in public health relations or perhaps by furnishing a flat financial subsidy, to the other extreme in which the hospital furnishes only the quarters and the health department provides all the personnel, supplies, drugs, and other material.

The numerous examples reported upon fall into two main groups: The first is in the field of clinic service which largely involves the diagnosis and treatment of disease, such as tuberculosis and venereal disease clinics. The location of such clinics in the organized out-patient department of a hospital makes available diagnostic and treatment resources which are seldom provided in their entirety for isolated clinics. The second type of clinic is exemplified by the baby health station or the

prenatal clinic in which the diagnostic and treatment facilities of the out-patient department are less important.

There appear, however, to these services as to the others, certain advantages from coöperation between the hospital and the health department; namely, economy to the health department (therefore to the community) through the use of the hospital plant and personnel, which otherwise would have to be provided by the health department. The same aspect of economy of plant and personnel applies to coöperation between health departments and voluntary health organizations, such as the Visiting Nurse Association, tuberculosis societies and others.

Representative examples of the coöperation illustrate a wide range of organizations involved and much diversity in the services jointly carried. Thus the health departments of Orange, East, West and South Orange and Maplewood, N. J., jointly support a venereal disease clinic at a voluntary hospital, the budget for which is prepared at the beginning of the year and each locality assessed on a per capita basis. The Orange Department of Health supplies social and clerical service, equipment, stationery and postage. The same hospital is active in programs for vaccination against smallpox and immunization of pre-school children against diphtheria, the health department supplying the material.

In Pontiac, Mich., one of the municipal well baby stations is conducted at the Visiting Nurse Association, the health department furnishing the medical nursing, and clerical personnel for tuberculosis and venereal disease clinics conducted at the county physician's office, and furnishes the quarters for a dental clinic conducted by the board of education and for an orthopedic clinic conducted by a county orthopedic association (Rotary Club). By agreement with a municipal and private hospital children are operated upon for the removal of tonsils and adenoids at a flat rate of \$3, the department paying for indigent cases.

In many states hospitals and dispensaries are coöperating with state health departments in the fields of tuberculosis, social and mental hygiene and orthopedic conditions in children. Thus, for venereal disease clinics in private hospitals the state department provides a subsidy in Brockton, Mass., the personnel in Chester, Pa., and Lima, O., and in Holyoke, Mass., \$1,000 annually. In Scranton, Pa., the state provides psychiatric social service for a mental clinic conducted by an independent dispensary under the direction of the psychiatrist in charge of the mental disease hospital of the Scranton Poor District.

The instances of correlated work in public health clinics between health departments and voluntary health agencies are both

and original in their application of coöperative principles. In addition to those previously mentioned in connection with hospital programs, the following may be cited as unusually suggestive. In Hartford, Conn., the Visiting Nurse Association furnishes the nursing service at cost to the health department for its infant welfare and preschool stations and for tuberculosis and venereal disease clinics conducted by the department at a voluntary dispensary maintained by the Community Chest. The state department also conducts a clinic for juvenile tuberculosis at the same dispensary in coöperation with the Visiting Nurse Association, and furnishes the salvarsan for the dispensary's venereal disease clinic.

In the larger cities coöperation in regard to clinics takes various forms. One of the most frequent is in the conduct by health departments of tuberculosis clinics in hospital out-patient departments, the hospital providing the quarters and the department the medical and nursing service. In Baltimore, Md., the department of health furnishes the medical, nursing and clerical personnel, supplies and drugs, and pays \$1,000 a year to a voluntary hospital for the maintenance of a tuberculosis clinic and a dental clinic for school children. Another hospital coöperates with the state in the operation of a clinic for venereal diseases, the state paying the cost. This same institution reports a close working relationship with the visiting nurses of the city and state health departments. There is an agreed area distribution of the city between hospitals and the health department in regard to prenatal care.

In Boston, Mass., a habit clinic conducted by one of the voluntary hospitals is furnished physicians and a psychiatric social worker by the health department. A dispensary receives \$1,000 a year from the state for a child guidance clinic, furnishing quarters, supplies and material, the state providing the personnel. The same dispensary conducts a cancer clinic, the state paying \$500 annually for rent of the radium used. This institution also holds a well baby clinic for which the city department supplies the personnel.

Other Forms of Coöperation—In addition to the relationships in three specific fields covered, it is reported that hospitals, health and social agencies and health departments are associated in such campaigns as May Day, preschool child health examinations, sight saving and immunization against diphtheria. Some of the unusual public health programs reported are in the following cities: Danville, Ill., where the attending staff of a private hospital held a course of free lectures in public health last year, a feature to be continued this year; Denver, Colo., where all public and private health groups recently conducted a series of meetings dealing with the question of medical service for chil-

dren attending the city's parochial schools; Rockford, Ill., which holds a "Better Health Week" in which all coöperate; and Covington, Ky., where a voluntary hospital carries on an active toxin-antitoxin campaign, the city appropriating \$300 for the service, in addition to an appropriation of \$2,400 for other work.

CONCLUSION

The committee does not think that this study has reached a stage at which specific recommendations should be made, defining the scope, policy and methods of coöperation between health departments, hospitals and other voluntary agencies. A few comments and suggestions have been made in the course of this report, but the committee wishes at present to make only one recommendation. It is urged that before the establishment or extension of health department services in the fields of laboratory work, care of communicable diseases or clinics of public health interest, consideration be given to the possibility of coöperation with hospitals or other agencies, with the aim of providing the maximum service to the public at the minimum cost.

Whatever value attaches to the present report will be in assisting the officers of both health departments and of hospitals to become familiar with plans of coöperation which have been found actually at work, to evident mutual advantage, in many places throughout the country. It is never wise to attempt to force coöperation. It is well that coöperative endeavors be conscious and considered instead of merely sporadic, and that they shall be able to learn from one another as to policies and methods.

NOTE: This is a condensation of the full report. Mimeographed copies have been prepared of the types of coöperation found in each of the 148 cities reporting, and are available to any member upon request.

Tattoo||Regulations

IN only one city in the country is tattooing prohibited, and in only three is it regulated, according to Marvin D. Shie, M.D., writing in the *Journal of the American Medical Association* for January 14, 1928. Dr. Shie points out that the number of infections due to tattooing is not inconsiderable, although less today than formerly. He suggests that the removal of tattoo marks should be undertaken only by a qualified physician, and that this work should fall within the scope of state medical practice acts.

A Suggested Monthly Check Sheet*

Based Upon Appraisal Form for Rural Health Work,
A. P. H. A.

H. S. MUSTARD, M. D., FELLOW A. P. H. A.

Health Officer, Rutherford County, Murfreesboro, Tenn.

THE primary object of this paper is to present a simple reporting device, the use of which will help the rural health administrator to maintain balance in his program and which will, at the same time, provide him with the data which he needs for monthly checking of particular health services. That the health officer has had difficulty on both these counts is generally admitted, and those engaged in administrative positions in the health field have given much thought to the problem of reports—what data should be reported and in what arrangement these data might best be presented.

It would seem almost axiomatic that a report should be made up of material representing accomplishments, and that this material should be so arranged that the reader might easily evaluate the work reported. An ideal type of report would contain figures representing results, listed by the reporter, and subjected to qualitative analysis and quantitative measurement by the reader. Such a scheme, however, carries with it certain inherent difficulties, the first of which is that results are not achieved upon a monthly basis. And too, many factors, uncontrolled, difficult of correlation and often unrecognized, enter into accomplishments which might appear to be the direct result of health work; and the administrator must be careful lest he make claims prematurely. For these reasons the usual monthly report is not set up to show the *results* of health work, but instead provides for the reporting of activities of the organization. If we are justified in assuming that a certain activity, if carried on continuously for a sufficient length of time, will attain a specific result, this practice seems sound; it is generally accepted.

In considering the methods of presentation of material in the monthly report, it becomes increasingly apparent that very few of those engaged in rural health work are satisfied with the type of reports used. From such presentation of figures it is difficult to determine organization trends or program balance. Monthly report forms at present in use

RURAL APPRAISAL FORM, A.P.H.A. REPORTING VITAL STATISTICS AND COMMUNICABLE DISEASES

ITEM	STANDARD	JAN	FEB	MAR	APR	MAY	JUNE	JULY	AUG	SEPT	OCT	NOV	DEC
BIRTHS REPORTED (WHITE)	50 PER MONTH	42/50	101/100	143/150	179/200	220/250	264/300	311/350	374/400				
BIRTHS REPORTED (COLORED)	20 PER MONTH	16/20	34/40	56/60	66/80	83/100	98/120	116/140	134/160				
CASES OF TYPHOID	7 PER DEATH	8/14	10/14	15/14	15/14	18/14	26/21	34/28	44/42				
CASES OF DIPHTHERIA	15 PER DEATH	2/0	4/0	4/0	5/0	5/0	7/0	10/0	11/0				
CASES OF SCARLET FEVER	50 PER DEATH	0/0	1/0	4/0	4/0	4/0	5/0	6/0	8/0				
CASES OF MEASLES	100 PER DEATH	2/0	23/0	55/0	89/0	99/0	100/0	100/0	100/0				
CASES OF WHOOPING COUGH	25 PER DEATH	22/0	31/25	36/50	36/50	41/50	43/75	44/100	45/125				

CHART I—ARRANGEMENT OF THE CHECK SHEET

The items selected are from the section of the check sheet upon which vital and morbidity statistics are recorded. The first or left hand column shows the items to be considered; the second column carries the monthly standard against which the item is to be checked. The standards for white and colored births are based upon population unit; the case rate standards for communicable diseases are common to all rural areas. The remaining vertical columns provide a block for checking each item month by month. It will be noted that each block is divided by a diagonal line, running downward from right to left, converting the report item for each month into the form of a fraction. In each instance the denominator represents an accumulation of the monthly standard of work to be done; the numerator represents actual accomplishment. For instance,

the monthly standard for colored births is 20. Therefore in January this number should have been reported. Actually, reports of only 16 colored births were received. For the month of February, the standard demands 20 more colored births, and the denominator accumulates to 40; the numerator for February is made up of the 16 reports received in January plus 18 more received in February. Thus at the end of the second month it becomes apparent that there had been received 6 births less than could be expected, and at the end of eight months the deficiency had become 26—the difference between numerator and denominator.

The communicable diseases case report standards require no particular explanation. It illustrates quite clearly that whooping cough is not reported satisfactorily.

show the record of monthly activity by item, and on the same line in a parallel column, the total of that item for the year to date. Some of these reports, for purposes of comparison, carry a record of activities for the corresponding month of the year past. Thus the reader of the report is furnished with figures setting forth so many cases of typhoid reported, so many school children examined, or so many immunizations against diphtheria. These data are valuable and interesting, but unless the reader of the report is familiar, in most minute detail, with the area reported upon, it is probable that he will not recognize the implication of many significant figures; nor will he be in a position to make

COMMUNICABLE DISEASE CONTROL

CHART II—ILLUSTRATIVE ITEMS ON FIELD WORK CONCERNED WITH THE CONTROL OF COMMUNICABLE DISEASES

The standard for visits to cases are those of the *Appraisal Form for Rural Health Work*. With the exception of typhoid immunization the other standards are based upon population. For instance, the yearly standard for consulting diagnostic service is 50 calls per 100,000 population. The population unit in Rutherford County is 32962. The total for the year in this county would be 17 or a little more than 1 per month. The standard for toxin-antitoxin im-

munization in preschool children is 20 per cent of the preschool population. The preschool population unit is 3461—total for year 692, approximately 60 per month.

Toxin-antitoxin in grade schools: 10 per cent of grade school population; population unit 7154; total for year 715; for month 60.

Smallpox: 3 per cent annually of total population; 990 per year; 90 per month (approximately).

a critical analysis of the situation reflected in the report, as he would be were there listed with each item reported a standard for comparison.

All of the above discussion is preliminary to consideration of such standards and their utilization in reports. The *Appraisal Form for Rural Health Work*, recently developed by the Committee on Administrative Practice, American Public Health Association, provides a most valuable instrument for measuring health department activities. Standards for activities are generally of two kinds: those common to all rural areas, as the reporting of 7 typhoid cases for every typhoid death, and those based upon population unit and consequently applicable only to the particular county or district concerned. Prenatal under supervision:
25 per cent of total births
Total births 738—Total for year 185
Approximate for month 16

Visits to Prenatal cases:
750 visits per 1,000 total births
Total births 738—Total for year 553
Approximate for month 47

Deliveries in Hospital:
10 per cent total births—Total births 738
Total for year 74—Approx. for month 7

Visits in behalf of infants:
1500 per 1000 live births
Total for year 1050

Approximate for month 88
Visits to Medical Conference:
2500 visits per 1000 live births
Total for year 1755

Approximate for month 150
Visits to Nursing Conference:
800 visits per 1,000 live births
Total for year 500

Approximate for month 42
Nursing Visits to Preschool:
100 visits per 1,000 preschool population
Preschool population 3461
Total for year 346
Approximate for month 30

ards are thus provided and can be used on a monthly basis. By simple computations other monthly standards are easily arrived at, usually by dividing the year's quota by 12.

In order to illustrate the practicability of the utilization of this standard in the monthly report, a number of charts have been prepared from the check sheet in use in Rutherford County, Tenn.

CHARTS VI AND VII

Most of the items presented on these two charts have been presented on others. In Chart VI are illustrative items representing those activities in which a nursing service is

concerned; Chart VII those items essentially medical. These items are grouped in this way for the guidance of division heads responsible for special fields within the general program.

In the application and interpretation of this check sheet method one should be careful lest he follow too blindly. Should the administrator be certain that an apparent deficiency in one activity is offset by concentration upon another it would be unwise to shift the program emphasis merely to score. On the other hand it should be recognized that the standards reflect group judgment, which is more apt to maintain balance than is individual opinion.

To avoid confusion it is necessary to state that this check sheet method is not a product of the Committee on Administrative Practice, and that this committee is in no way responsible for its deficiencies. Consideration of this method of reporting should not be confused with the soundness or lack of soundness of the standards set forth in the *Appraisal Form for Rural Health Work*, nor with the accomplishments or deficiencies in that particular county whose figures are shown.

American Association for Medical Progress

THE American Association for Medical Progress, Inc., a national lay organization, with headquarters at 370 Seventh Avenue, New York, N. Y., during the year 1927 contributed articles, supplied educational material for exhibits, and conducted lectures on the relation of experimental science to human welfare. Two pamphlets explaining the contribution of science to the control of smallpox and diphtheria were issued and widely distributed along with other publications of the association. Although the association does not formally engage in research, it assembled a considerable amount of available data on smallpox vaccination laws, on the previous vaccinal condition of smallpox patients, on authenticated cases of disasters supposed to have resulted from the use of toxin-antitoxin, and on the availability of dogs for medical schools and for research, with special reference to legal limitations, legal recognition of research needs, and extra-legal arrangements that interfere with research. One of the better known activities of the association was its coöperation in establishing a voluntary fund for the purchase of a home for John R. Kissinger, the first private who offered himself for experimental exposure to yellow fever inoculation under Major Walter Reed in 1900. The purpose of the association, as stated in its annual report for 1927, is "to encourage experimental research for the advancement of medical science; to inform the public concerning the methods and discoveries responsible for man's increasing control over animal and human diseases."

An Intensive Newspaper Crusade for the Control of Cancer

GEORGE A. SOPER, PH.D., FELLOW, A. P. H. A.

American Society for the Control of Cancer, New York, N. Y.

AT a meeting in the spring of 1927 to stimulate interest in an organized campaign to raise an endowment fund of \$1,000,000 for the American Society for the Control of Cancer, a wish was expressed that a number of the addresses which were made by surgeons and research men could be printed in the daily papers. Out of this came the suggestion that the newspapers might print authoritative articles if a series could be produced which would be at once short, interesting, and informative.

To promote this idea a conference was held in New York City between prominent representatives of the publishers of the principal New York papers and of the American Society for the Control of Cancer.

A plan was evolved which called for sixteen articles on as many aspects of the cancer question. They were not signed but issued in the name of the American Society for the Control of Cancer. The articles were all to be carried under a suitable slogan. They were to be numbered and set up in two-column boxes. Each was to conclude with an announcement of the subject of the article which would appear on the following day. All the papers were to begin on a given date and proceed to print the bulletins in orderly sequence. One main idea was to run through the whole series and be stressed by reiteration and variation of expression: many cases of cancer can be cured if people will seek skillful medical attention upon the appearance of the earliest symptoms.

In due course the articles were written. Each was about 250 words in length and in all a tone of hopefulness was employed. The titles follow:

The Prevalence of Cancer
What Is Cancer?
The Danger Signals of Cancer
Is Cancer Hereditary?
Is Cancer Contagious?
The Family Doctor in Cancer
The Prevention of Cancer

The Surgical Treatment of Cancer
Cancer Clinics
Cancer Research
X-Rays and Radium in Cancer
The Warfare Against Cancer
The Curability of Cancer
Cancer Quacks

Following is an example of the bulletins showing the typographic set-up:

THE NEW IDEA OF CANCER
MANY CASES CAN BE CURED IF REPORTED PROMPTLY

Bulletin No. 5—New York Campaign
American Society for the Control of Cancer
25 West 43rd Street, New York City

IS CANCER CONTAGIOUS?

In spite of the fact that physicians and nurses have come into intimate contact with cancer patients for so many years and taken no precautions against infecting themselves, there is no recorded instance of one case of cancer giving rise to another.

This is not to say that microbes are never found in cancers. Discoveries are announced from time to time that bacteria have been identified with cancer, but upon full and impartial investigation it is always found that these parasites have been invaders of the cancer growth—followers rather than producers of the malignant condition.

Cancers often become infected with such microbes as infect wounds of any kind and the unpleasant odors which are sometimes associated with cancer are due to these accidental contaminations. Consequently, the precautions to be taken by those who come in contact with cancer patients are only such as should be followed with infected wounds.

There is no occasion to shun a person who has cancer, so far as danger of contracting the disease is concerned. The victims need all the sympathy and tenderness which can be shown them. Fear that cancer was contagious has sometimes led to unnecessary and uncharitable action toward the sick.

THE TIME TO CURE A CANCER IS WHEN IT IS BEGINNING

If you think you have any of the symptoms described in these articles you should be examined by your doctor or at a hospital at once.

Tomorrow's Article—"The Family Doctor in Cancer"

It was intended to print the bulletins in the spring, but the flight of Lindbergh to Europe took up so much of the space of the newspapers that by the advice of the publishers their appearance was postponed until fall.

It was expected that the publication of the bulletins would send many people to the hospitals. Accordingly, it became necessary to have the hospitals prepare to receive an unusual number of cancer cases and to make special provision for diagnoses.

It was also necessary to stage educational activities of various kinds in order to supply news which would give something for the papers to tie the bulletins up to, as the editors expressed it. They would be liberal in devoting space to cancer, but they must have news items to use in the preparation of their articles.

Inasmuch as the bulletins could not be printed until the autumn, opportunity was afforded to make careful plans for these features.

The postponement brought about a slackening of interest in the project, and it was thought necessary to do something to arouse the attention of the editors and publishers. Accordingly a letter was sent to each publisher in September informing him that during October Dr. George A. Soper, Managing Director of the American Society for the Control of Cancer, would make four addresses before medical societies in different parts of the country on topics which would be suitable for newspaper notice, and that abstracts of these addresses would be released in advance. The titles of these papers were:

Analysis of 1500 Applications for the Saunders Cancer Awards

The New Aspects of the Cancer Problem

What Official Public Health Agencies Should Do About Cancer

The Organized Movement for the Control of Cancer in America

Clippings subsequently received at headquarters showed that these addresses received considerable notice. When added together, the clippings amounted to 867 column inches.

The publishers were consulted on various subjects immediately before the bulletins were to be released, as, for example, the most favorable day for the appearance of the first bulletin, the suitability of the set up, and the order in which the bulletins should appear. It was hoped that in this way their interest would be further enlisted.

To give news support to the bulletins, the New York City Committee of the American Society for the Control of Cancer was requested to put on a period of intensive educational activity consisting of public meetings and other features of the society's cancer weeks. These "weeks" had long been familiar to other parts of the country but were new to New York City. The New York Committee was also asked to get the hospitals ready to handle the many persons who might apply for diagnosis and advice.

A series of articles was written to be released to the newspapers as news stories during the fortnight over which the bulletins would appear. These included the remarkable case of the "Wizard of Hicksville," a man who had courageously had a large part of his stomach removed because of cancer and had just opened a little machine shop in the village where he lived, and a report of advance information on cancer mortality, in which crude, adjusted and refined rates were given.

The New York City Committee brought about a number of public meetings, gave radio talks, and put up many posters and car cards. Reporters were referred by the national office of the society to the city committee for local news. It is in no small measure due to the coöperation afforded by the New York City Committee that so much space was given to the campaign by the metropolitan papers.

When all was ready, the printing of the bulletins was started. It

was expected that there might be a hitch and there were several. At the last moment one of the principal dailies reversed its decision to carry the bulletins. It refused to print any of them. The editors feared that their publication would do more harm than good—that the public would be unduly alarmed. Cancerphobia was as bad as cancer itself.

Here was a difficult situation. The newspaper in point was the most important of all. The refusal had been recommended by the editors and confirmed by the publisher. If this paper would not print the bulletins some or all of the other papers might also refuse to do so. On the other hand, if all the New York papers would go into the scheme, dailies and weeklies outside of New York might be induced to do the same.

An interview was obtained; the importance of the subject was explained; a slight change was proposed in one of the bulletins and reconsideration given to the whole subject. A decision was reached on the part of the publisher not only to print the bulletins but to give a column of news space a day to the subject of cancer as long as the bulletins were being printed. The way in which this final decision was carried out is above all praise. Not only was much space given to the subject in the news columns of this paper, but in addition several excellent editorials were printed. The paper was the *New York Times*.

Disaster threatened in another direction. On the eve of the appearance of the first bulletin, several morning papers raised the objection that they could not reprint bulletins if they were first to appear in the previous evening papers. The evening papers refused to reprint bulletins which were first carried by the morning papers. Each set of newspapers was willing to print the bulletins on the same day that others published them, but no paper would publish anything which had already appeared.

There was only one thing to do. A second set of sixteen bulletins had to be hurriedly prepared. The new set was much like the first one as to topics and their order but had a different slogan and was different in composition. This solved the difficulty.

There were some minor hitches, but by diligent use of the telephone they were overcome. One by one the newspapers got into line after the four principal ones led off. By the end of the first week nine of the city papers were printing the bulletins.

When practically every newspaper in New York City was carrying the bulletins, the idea was taken to the whole country. Copies were sent to the society's state chairmen with a request that they send the bulletins to the newspapers in their territory asking the publishers as a personal favor to publish them. They could point to what was being

done in the City of New York as an argument. Prominent people in various occupations were urged to write to the publishers expressing interest in the matter. Bulletins were also sent direct to newspapers.

The response was gratifying. Newspapers, and sometimes syndicates of newspapers, took up the bulletins and printed them. The movement gained impetus as it proceeded. Dates of release were disregarded to the extent that previous publication in New York City or elsewhere was not considered a bar. More and more papers carried the bulletins each day. Messages arrived at headquarters requesting sets of the bulletins for the use of papers which had inadvertently been omitted from the list of those to whom sets had been sent. Some publishers were offended at having been left out.

It is impossible at this writing to state how many papers printed the bulletins. There are many periodicals which appear once a week which are still joining the movement, and there are a great many little newspapers which will follow the example of the big ones.

Up to March 1, 507 papers were known to have carried or to be carrying the bulletins. These newspapers were distributed in 43 states. All of these papers except the New York City morning papers were carrying the series originally prepared. The aggregate circulation cannot be given, as all returns have not been received at headquarters, but it is known to be well over 10,400,000.

Advertisers and others estimate that the number of readers for each paper varies from 3 to 5. The number who read a given paper depends upon the paper itself, the part of the country in which it is published, whether it is a morning or evening issue, and whether it is delivered at the home or bought at a stand. Allowing 4 readers for each paper, the total number of persons into whose hands these bulletins have been placed has been, roundly, 42,000,000 a day. It is to be remembered that this distribution has taken place not only on one day but on sixteen days.

The value of this publicity cannot be estimated in terms of money, nor in any other way, but a few remarks upon its practical utility may be of interest. During these two weeks probably as many people were instructed in the society's doctrine as had been reached through all channels during any period of five years of the society's career. This instruction had the advantage of being given directly by the national office to the persons for whom it was intended and not through the interpretative voice of a lecturer or other intermediary. The lesson had the value of reiteration. The instruction was exactly in the direction followed by the society from its organization fourteen years ago; namely, the public was told the danger signals of cancer and advised

to go to a physician or hospital for examination upon the first appearance of symptoms or, in fact, a suspicion that cancer might be present.

That many people have been frightened into going to the doctors and hospitals, there is no doubt. Nor is it to be doubted that lives have been saved thereby. The intention has been not to alarm people unduly, but just enough to cause them to have a proper regard for their safety so that they will take the necessary steps for their protection.

Hundreds of people telephoned or called or wrote letters to the office of the American Society for the Control of Cancer asking for further information. Many inquirers wanted to know where to go for examination. A list of 46 hospitals with their addresses and clinic hours had been prepared in advance for such persons and these were given out on request. The hospitals had been requested to be ready for the patients who might come to them. Nobody was sent to any one doctor or hospital. The society did not make any diagnoses or give medical advice suited only to particular cases; much less did it, or does it ever treat cases. Questions on every conceivable aspect of the cancer problem poured in. Provision had been made to answer all inquiries promptly and fully.

There were very few editorials. This feature was not especially promoted in connection with the scheme, this being thought to be unnecessary. It was mistakenly supposed that the editorial page would back up the news pages by recommending the bulletins and their teachings to the sensible attention of the readers.

The hospitals all reported an unusual number of persons applying for examination for cancer. It is believed that not a few persons appeared in an early enough stage in the disease to permit of cure.

On the day when the last bulletin of the series was published in the New York City papers a letter was received by the society from a well known firm of lawyers asking for the full legal name of the American Society for the Control of Cancer, explaining that because of the recent newspaper crusade a client had decided to change his will so as to leave the society a legacy of \$50,000.

The preparation of the bulletins, the contacts with the newspapers, and the large amount of correspondence involved were all attended to by the society's regular staff. There was no publicity expert employed and no extra help of any kind engaged upon this work.

The newspaper space known to have been given to the bulletins and their supporting news releases was as follows:

Addresses by Dr. Soper, 867 column inches; daily bulletins, 30,560 column inches; news, 2,425 column inches; totalling in all 33,852 column inches.

Hunting the Vitamin*

WALTER H. EDDY, PH. D.

Teachers College, Columbia University, New York, N. Y.

AN OUTSTANDING event of 1926-27 in vitamin research has been the ^{chemical} ~~fractionation~~ ^{fractionation} of complexity in what we have been wont to designate as Vitamin B or, in Funk's nomenclature, the antineuritic vitamin. Smith and Hendrick¹ in this country probably first produced satisfactory evidence of at least the duality of the complex though Emmett and others had some years before noted the possibility. Goldberger and his coworkers² have extended these studies of Smith and Hendrick and shown that one of the vitamin B factors is relatively heat stable, non-antineuritic but definitely antipellagric. This viewpoint has been confirmed by other workers in both this country and in Europe.

From Java also comes this year the announcement of the isolation of the antineuritic factor in crystalline form, reported by Jansen and Donath.³

It is then at least evident that what we have called vitamin B consists of two vitamins and that these factors are distributed in food sources of the vitamin in differing proportion. A food in other words may be a good antineuritic and a poor antipellagric or *vice versa*. It is however still far from certain that what we have called vitamin B is merely dual in nature. The data already obtained however strongly emphasizes the need of chemical fractionation of these factors if we are to learn their rôle in diet and health.

During the past seven years R. R. Williams has actively coöperated with my laboratory in the study of vitamin B fractionation. Independently and in collaboration he has accumulated a vast amount of data involving over 1000 pigeon feeding tests and many rat feeding tests. The detail of this experimentation has an important bearing on both the chemistry and physiology of vitamin B factors and will soon appear in print.

Dr. Ralph Kerr, who developed with Williams and myself the isolation of a crystalline bios (bios 223), has during the past year separated from yeast another substance of chemical homogeneity and

* Read before the Food and Drugs Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

while his work has not yet reached the point of complete purification of the substance or of chemical designation comparable to what exists for bios 223, the new product (beta bios) is quite different from the first and apparently of greater growth stimulating power.

In a sabbatical leave tour of France and England during the first of this year, I had the opportunity of personally observing the methods and results of Randoin, Besszonof, Drummond, Chick and Peters and other workers in the field.

In view of the above it has seemed to me not out of place also review some of the data now existent concerning the vitamin B complex and especially the work of my own laboratory as it relates to work of other laboratories now studying this problem from the chemical angle.

At the Lister Institute in London, in May, 1927, Dr. Harriet Chick, in collaboration with Miss Roscoe had obtained data apparently fully confirming Goldberger's contention that the yeast vitamin B is composed of an antineuritic factor and an antipellagic factor. Her work makes clear that both of these factors are necessary for continuous growth in rats and that the antipellagic factor is more heat stable than is the factor which prevents or cures polyneuritis, but it is both misleading and contrary to fact to designate the antipellagic as the growth factor in contradistinction to the antineuritic factor, for so far as her experiments go they show that the rat will decline and die unless both factors are present in suitable proportions. Her studies also show that wheat embryo is much richer in the antineuritic factor than in the antipellagic one, thus putting wheat in the same category as corn in this respect.

It may be recalled here that Goldberger's success in demonstrating the P-P factor (his designation for the antipellagic) lay in his utilization of an alcoholic extract of cornmeal which, like Chick's alcohol extract of wheat embryo, proved relatively poor in P-P but rich in antineuritic. Chick's experiments are however in a way still more conclusive owing to her possessing a source of antineuritic *practically devoid of P-P*. This she owed to the success of Kinnersley and Peters of the Oxford University Department of Biochemistry. In this country we have known for some time that by autoclaving yeast at 120° C. we can destroy its heat labile polyneuritis preventing power without loss of its more heat stable P-P factor. We have however lacked a preparation that was rich in antineuritic but entirely devoid of P-P. Kinnersley and Peters's "torulin" yeast fraction therefore particularly interested me. Their preliminary method has already appeared in print but Peters has since greatly refined this method and has kindly provided me with details of his present method including his manner of con-

trolling the selective adsorptive power of norite for the antineuritic factor. His present method is briefly summarized below:

SUMMARY OF PETERS AND KINNERSLEY'S PRESENT METHOD OF OBTAINING "TORULIN"

1. Extract partly autolyzed baker's yeast with boiling water. Filter.
2. Treat filtrates with 25 per cent neutral lead acetate. Filter.
3. Treat with baryta to remove gum. Filter and make acid to Congo red with sulfuric.
4. Remove baryta with sulfuric acid. Filter. Make solution pH 2.5.
5. Add mercuric sulfate in sulfuric acid. Filter.
6. Make filtrate pH 7. Add dry purified norite. Filter after 10 minutes' stirring.
7. Re-treat filtrates with additional norite to complete removal of torulin at pH 7.
8. Extract torulin from norite with N/10 HCl on hot water bath.
9. Purify torulin by alcoholic fractionation method after the manner of Osborne-Wakemann.

My interest in this "torulin" fraction and Chick's use of it was further stimulated on my return from Europe by finding that my colleague Williams had in my absence also succeeded in accomplishing a fractionation of the more heat labile part of vitamin B by refinements in the control of the adsorbing power of fuller's earth. Almost coincident with these developments came the announcement by Jansen and Donath of the isolation of a crystalline antineuritic of high potency.

Are Peters's "torulin," Williams's specifically activated fuller's earths, and Jansen and Donath's crystalline antineuritic, identical in character? Unfortunately data are not yet available to settle this point. Peters tells me that he has been unable to make Jansen and Donath's method produce a product such as they describe when he has applied it to his norite fraction. Since however, the method of Jansen and Donath was applied to rice polish extract, Peters's failure may be due to interference with the method by substances present in yeast and absent in rice polish. Peters has also confined his tests for potency to measurements of dosage necessary to cure pigeons sick of polyneuritis in a given time period. He has, so far as I can learn,⁵ reported only two observations on the weight restoration or weight-maintaining power of his torulin fraction and in these two cases the birds were cured of polyneuritic symptoms but continued to decline in weight. Jansen and Donath report only a few observations on pigeon weights but imply that their fraction not only cured polyneuritis but also prevented weight loss.

The properties of Williams's preparations⁶ are presented in the accompanying Chart I, and will be described much more in detail in his own report of these findings. His preparations used in preventive

TO SHOW THE SPECIFICITY OF WILLIAMS'S PREPARATIONS WHEN USED IN TESTS
WITH PIGEONS

CHART I—Four adult pigeons were fed on polished rice alone until the 16th day. On the 16th day each bird received 5 mg. of Williams's preparation Y1 and this dosage was continued daily up to the 42nd day. The birds ceased to decline in weight and showed no polyneuritis but failed to return to normal weight. On the 42nd day the dose of Y1 was quadrupled (20 mg. daily) and on the 49th day quadrupled again (80 mg. daily). These increases failed to appreciably restore weight. Addition of autoclaved yeast on the 58th day also failed to restore weight but the birds promptly recovered when fed whole grain or whole dried yeast. Pigeons therefore require what is in Y1 to protect from polyneuritis and to maintain weight but Y1 lacks a factor present in whole yeast and in autoclaved yeast which the pigeon needs. Is this vitamin B3? The heavy line in the chart is the growth curve.

tests uniformly exert some power toward the restoration of weight or at least to maintaining of weight at a lower level than normal, but in no case or dosage yet tested are they capable of bringing the birds back to the weight they had before the polished rice feeding began. With rats Williams's preparation produces, when used as the sole source of vitamin B in an otherwise adequate diet, a slight amount of growth. Autoclaved yeast alone also stimulates growth at first but a growth that is soon arrested and followed by death from polyneuritis. By combining the Williams preparation with an adequate supply of autoclaved yeast

normal rat growth is obtained. It prevents polyneuritis in both rats and pigeons in doses as low as 5 mg. of activated earth per day.

Chick's work shows that Peters's extract resembles Williams's fraction when supplied to rats, i.e., it is lacking in the heat stabile factor of autoclaved yeast. Seidell's experiments and ours make it doubtful whether the P-P factor of autoclaved yeast is required by pigeons. To date it has been found impossible to restore birds to normal weight by adding autoclaved yeast to the Williams factor in pigeon feeding. Hence in the lack of further data from Peters we know only that his torulin fraction behaves like Williams's fraction toward rats but not that it is identical in bird affecting values. In brief, it is still a question whether the heat labile factors required by pigeons are one or two; whether the vitamin B complex of yeast is composed of two heat labile and one relatively heat stabile* factor, one of each or several of each.

Significant then as are these fractionations in the matter of solving the problem of what vitamin B is, that problem still exists. There is neither time nor place here for further discussion of these points. It will however be immediately evident to the public health worker or dietary adviser that we must have a complete revision of our tests and data on the distribution of vitamin B in foodstuffs and that the preparations described above are going to be valuable tools in this work. Previous tests have taught us the amounts of food considered as source of vitamin B necessary to normal or subnormal rat growth or to pigeon health, but not their antineuritic versus their antipellagric content. I wish then to consider next some of our preliminary work in approaching this problem of differentiating the vitamin fractions.

A year ago I reported to this Association a series of experiments devised to show the vitamin value of the banana.⁵ In that report I showed that by the Sherman rat test 8-10 g. of ripe banana per day per rat was necessary to prevent polyneuritis and secure a growth of 20 g. gain in 60 days using 30-day old white rats as test animals. How much antineuritic and how much antipellagric vitamin is present in this quantity of banana? Obviously the gross test of last year shows that both factors are present in banana but fails to differentiate them. With the aid of Williams's preparations and autoclaved yeast we now have tools that enable us to do this. Chart II summarizes the feeding tests to date. In brief, if the antineuritic factor is supplied by an adequate source such as Williams's preparation which is at the same time free of

* It will be noted that we are careful to describe the P-P factor as relatively heat stabile. Ordinary autoclaving of yeast adequate to destruction of its polyneuritis preventing power leaves the yeast antipellagric. An accident in allowing the autoclaving to proceed for a longer time demonstrated that under these conditions the antipellagric power will also disappear. P-P is then capable of heat destruction but far more resistant to it than is the antineuritic fraction.

TO SHOW THE SPECIFICITY OF WILLIAMS'S PREPARATIONS WHEN USED IN TESTS WITH WHITE RATS

CHART II—A. Three rats 30 days of age were fed on a vitamin B-free basal diet plus 10 mg. Williams's preparation Y1 daily. On the 30th day the Y1 was quadrupled (40 mg.). A slight temporary gain was not maintained but no symptoms of polyneuritis appeared. Y1 then protects rats from polyneuritis, permits some weight gain but is not adequate for normal growth. B, C, D, E. These four groups of 30-day old rats were fed as follows: Group B received the same basal diet as Group A, plus 1 g. of autoclaved yeast daily. They received no Williams's preparation. They declined in weight and died of acute polyneuritis in 25–40 days. Groups C, D, and E received the same basal diet and autoclaved yeast dosage as Group B. In addition Group C received 3 mg. Williams's Y1 daily, Group D received 6 mg. Y1 daily and Group E 10 mg. Y1 daily. When the rat receives his antipellagric factor in the form of autoclaved yeast and his antineuritic factor in the form of Williams's preparation normal growth results. He apparently needs only vitamins B1 and B2 and does not require the factor B3 essential to the pigeon.

P-P, even 2 g. of banana per rat per day supplies enough of the latter factor to produce better than 20 g. gain in 60 days and 6 g. of banana furnishes enough P-P for nearly normal growth curves. The banana should then be a good antipellagric. On the other hand, if P-P is supplied by autoclaved yeast devoid of antineuritic, rats fail to show an upward growth trend until at least 6 g. per day of banana is added to supply antineuritic. The differentiation of vitamin B in a fruit such as the banana then seems to indicate a better content of antipellagric than of antineuritic. Does this hold true of other fruits? Tests of course will be our only means to the answer, but the tools are now available for the tests.

We have as yet had time to test only one other foodstuff by this method. In our study of the distribution of vitamins in canned spinach, Kohman and I¹ reported some time ago certain observations on its vitamin B content. At the time we noted a marked difference in the behavior of dried raw spinach and dried cooked spinach as a source of vitamin B with an apparent lessened potency of the latter. We did find however that the canned was as good as the home cooked in this respect. In carrying our control experiments we made the discovery that if a rat received *one-third* of his vitamin B requirement in the form of dried yeast, he not only was able to use dried cooked spinach to meet the other two-thirds requirement, but would readily eat enough to bring about this result. We felt at the time that the yeast was a means of stimulating the appetite of the rat for spinach rather than that the spinach was lacking in B. We did however record at the time one experiment of Williams with our dried cooked spinach in which he was unable to prevent polyneuritis in pigeons with a daily dosage of 4.4 g.

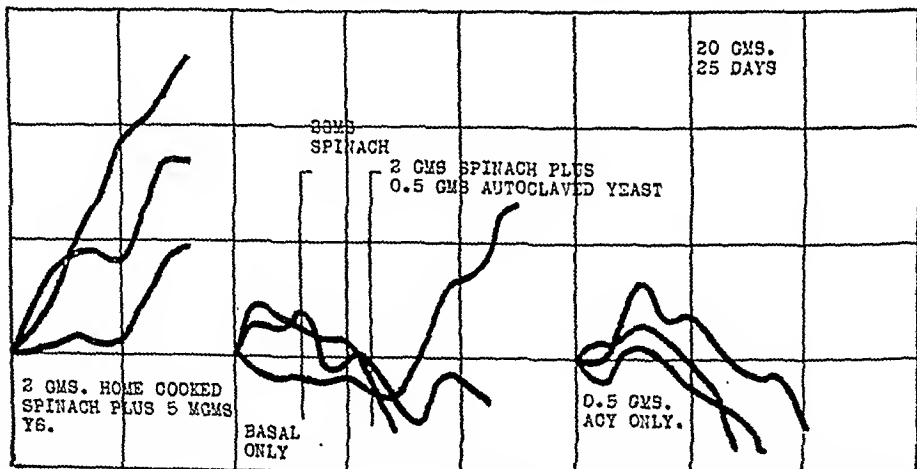

Pigeon and rat testers have frequently reported similar discrepancies in studies of vegetable and fruit sources of vitamin B. We have therefore, as in the case of the banana, begun a series of tests of the vitamin B value of spinach using similar methods and utilizing autoclaved yeast and the Williams preparations in tests. Chart II shows data obtained to date using undried home cooked spinach in this series. Again we find that while the spinach is not devoid of either factor, it is a much better source of the antipellagric than of the antineuritic, and that cooking tends to reduce its antineuritic value.

The purpose of this paper is primarily to show the importance of chemical fractionation methods in progress toward the solution of problems of vitamin behavior. Perhaps these two illustrations have adequately indicated how hunting the vitamin B fractions has been a step toward better dietetic advice and a means to further progress in that line. Since, however, we are not at all sure as yet as to how many

APPLICATION OF WILLIAMS'S PREPARATIONS TO VITAMIN B TESTS ON FOODSTUFFS

TESTS ON RIPE BANANA SHOWING IT TO BE A BETTER ANTIPELLAGRIC THAN AN ANTINEURITIC
THOUGH CONTAINING BOTH FACTORS

TESTS ON UNDRIED HOME COOKED SPINACH SHOWING IT TO BE A MUCH BETTER ANTIPELLAGRIC
THAN ANTINEURITIC

CHART III—Since the Williams's preparation Y1 supplies the rat with antineuritic factor only and the autoclaved yeast with antipellagric factor only it is possible with these two substances to determine quantitatively the amount of each kind of factor present in a food stuff. Chart III shows how these factors were used to show that both banana and spinach are richer in antipellagric than antineuritic factor. By giving the rat in combination with an otherwise adequate basal diet enough of either factor to meet his need for that, the value of a foodstuff as supply of the missing factor is measurable.

vitamins B exist, it is perhaps well to emphasize both their value and limitations. The latter consideration gives point to the urge to greater activity in the field of chemical isolation and before closing this paper I wish to report briefly certain other chemical phases of our vitamin hunt attained during the past year.

Sir James Irvine recently put his reasons for interest in the study of carbohydrates as follows:

My reflections have convinced me that first importance must be attached to the fact that carbohydrates are essentially the products of natural, as opposed to artificial, synthesis. Within us and around us, through the agency of life, these compounds are being built up and broken down, formed and transformed, finally to be consumed in the fire of metabolism. To study the sugars is, in brief, to study the great molecular channel through which solar energy flows to us. No wonder that the thought of such work makes a powerful appeal to the student of vitalism who is naturally somewhat inclined to turn aside from that aspect of chemistry which deals with purely artificial reactions.

The study of yeast behavior and the factors that control it has for a somewhat similar reason to that advanced by Irvine, always interested the biochemist. The postulation of bioses that function in stimulating yeast growth, much as vitamins stimulate the growth of higher organisms, has held out the hope that by isolation and observation of the behavior of these bioses we might obtain more easily the clue to the method of activity of the vitamins even though, as now seems evident, such bioses do not appear to be of importance in animal nutrition.

Three years ago Kerr, Williams and I⁹ succeeded in isolating from yeast a crystalline amino acid that seemed to function as a bios. A later discovery was the fact⁹ that the activity of this compound could be completely blocked by substituting for one of its NH_2 hydrogens an additional compound (benzene sulfon chloride) and that this inactive compound became active again when the substituted product was removed and the hydrogen restored by hydrolysis. Such studies seemed to be bringing our hunt closer to localizing the seat of activity of these compounds. However, a series of events has postponed for the time our pursuit of the study of bios 223.

By following our method exactly Roger Williams¹⁰ was able to separate from yeast our crystalline bios or at least a product with the same physical and chemical constants. When he tested the activity of this product on the yeast at his command he reported two results of significance, viz., that the isolated amino acid is not so active as the yeast autolysate from which it is separated and that its stimulative power is confined to certain strains of yeast. His findings are given in part in Table I.

TABLE I

ROGER WILLIAMS'S RESULTS WITH BIOS 223 TESTS

I. 24 hours incubation at 31° C.		II. 48 hours incubation at 31° C.	
Test	Yeast crop in mg.	Test	Yeast crop in mg.
Control (no bios)	1.0	Control (no bios)	1.7
10 mg. yeast autol	2.1	1 mg. bios	2.7
0.5 mg. bios	1.4	1 mg. bios	2.9
0.2 mg. bios	1.6	10 mg. cane molasses	3.3
0.06 mg. bios	1.3	20 mg. cane molasses	4.1

Meanwhile, unaware of Williams's results at the time, our own tests had revealed similar peculiarities as well as other data of interest in the matter of bios behavior. Some of these data are given in Table II.

The results showed conclusively that our bios 223 isolated from yeast autolysate either was not the sole bios or lacked some factor left in the yeast to attain maximum stimulation. The results also strongly suggest that these bioses are not growth catalysts but true yeast foods, the stimulation being directly proportional to the amount of bios present. In view of these results it seemed best to turn for the moment from the study of structure of bios 223 and hunt for another bios in the yeast autolysate. That search has been successful and will shortly be reported in detail by Dr. Kerr. The following brief summary will show how the new product (beta bios) was obtained and in Table III are given a series of comparisons between its behavior as a growth stimulus and bios 223. Chemical analysis indicates homogeneity in fractions obtained by duplication of the isolation method and certain indications as to its structural composition are now available, but it is unlike bios 223 in being very hygroscopic, and we have not yet suc-

BRIEF RECAPITULATION OF KERR'S PRESENT METHOD OF SEPARATING ALPHA AND BETA BIOS FROM YEAST AUTOLYSATE

I. Preparation of extract which contains both bioses:

- Autolyse brewer's yeast 3 days at room temperature. Filter.
- Dilute with equal volume of water and refilter.
- Heat filtrate to boiling and discard unfilterable matter.
- Stir with 50 g. fuller's earth per l. (750 g. per extract 100 lbs. moist yeast.) This process removes the vitamin B and takes out little bios.
- Make filtrate pH 4.7 and stir with iron sol. Discard ppt.
- Make filtrate pH 5.3 and use double amount of iron sol. used above. At this pH the iron sol. in suitable quantity removes both bioses. Adsorption complete if stirred and then allowed to stand 30 minutes before filtering. Activated iron sol. further purified by mixing with water, stirring and again filtering.
- Obtain bioses from iron sol. by first drying the latter. While still pasty add as little as possible of 30 per cent sulfuric acid. When solution is

nearly complete, dilute with water until sulfuric acid content is not over 5 per cent. Remove iron and sulfate ion with baryta at pH 7. Filter only at this pH. Beta bios is lost if filtered at alkaline reaction.

II. Separation of the bioses from the above extract:

- a. Remove baryta with sulfuric acid and concentrate at 50° to sirupy consistency. Add 95 per cent alcohol and satt. baryta (hot) until alcohol content is 70 per cent and no more baryta gum flocks out. Let ppt. settle. Decant and filter the supernatant fluid. The precipitate now contains the beta bios. The filtrate contains the alpha bios (bios 223).

III. Purification of beta bios:

- a. Stir ppt. with water and filter. Repeat until water filtrate is colorless.
- b. Neutralize filtrates as rapidly as possible with sulfuric and combine.
- c. Make combined filtrates pH 5-6 and filter.
- d. Add hot water solution of silver sulfate and reject ppt.
- e. Add acid mercuric sulfate to filtrate and reject ppt.
- f. Evaporate extract from 100 lbs. yeast to 100 c.c. Add sulfuric to 5 per cent by wt. Precipitate with 20 per cent phosphotungstic acid in 5 per cent sulfuric. Let stand over night and filter. Save ppt. Discard filtrate.
- g. Decompose the phosphotungstic ppt. as follows:
Dissolve ppt. in as little 80 per cent acetone as possible and add cold 1/3 satt. baryta. When the mixture is free of soluble phosphotungstate evaporate with constant stirring and air blast until free of acetone. Filter and discard ppt. Remove barium quantitatively with sulfuric and concentrate filtrate to sirup by fanning at 30° C. (Compound is very thermo-labile.) Do not attempt to carry this to dryness. Dry the product by stirring in large quantities of acetone until the residue becomes a dry granular yellow powder. Filter the acetone suspension by suction until the last free acetone disappears from the top of the ppt. While the residue is still moist with acetone transfer to a cool dry container and place immediately in vacuum desiccator over fresh sulfuric acid. Remove last traces of acetone suction. Light yellow semi-crystalline powder is beta-bios.

Are there other bioses in yeast? Are these two products similar in function? Are they related in any way in origin? Do they exist in yeast as separate entities or are they parts of a larger molecule split by our fractionation? These and other questions at once arise but the success of the hunt in bringing to light another homogeneous complex of growth stimulating activity has at least multiplied our tools for the study of the chemistry of growth stimulation and perhaps justified delay in the solution of structural problems raised by bios 223 isolation.

I believe that the explanation of the rôle of factors such as vitamins and bioses in nutrition can come only with chemical isolation and perhaps synthesis of the active substances. I feel that the past year has provided distinct encouragement that such isolation is possible, and that we merely await with further patience the refinement of existing procedures to attain the goal. I might have cited equally notable advances in this direction in the study of other vitamins by other

workers. However, in adhering to the rule of the Association that the paper shall deal with original work I have confined my review as much as possible to the developments in my own laboratory with such reference to other work in the field as relates to it.

The significance of this and other work on vitamin structure and behavior perhaps needs no further words of interpretation to workers in public health fields. The true student of the science of nutrition, however, often appears to a disadvantage in the rôle of adviser on dietetic problems due to his consciousness of unsolved problems, an inhibition entirely lacking in the dogmatic food faddist. Perhaps then it is permissible to emphasize a bit the need of such inhibitions and the problems that still exist unsolved to encourage the public health worker to continue to be cautious rather than dogmatic in his advice.

Paris Has New Type of Open Air School.

A NEW type of open-air school, sponsored by Prof. Alfred Binet, co-inventor of the Binet-Simon Intelligence test, has been opened recently in a thickly populated district of Paris.

The purpose of this school is to provide instruction for each child not according to his age, but according to his physical and mental abilities. Each pupil is examined by a physician at the time of admission; is given a Binet-Simon test; and is then assigned to a grade in accordance with the findings of the examination. The examination is repeated every 3 months, and the child is promoted to a higher grade or left in the same, according to the findings.—*La Pediatria*, Naples, Oct. 15, 1927. p. xxvii.

The School Ventilation Study in Syracuse, N. Y.*

School Year, 1926-1927

THOMAS J. DUFFIELD

*Executive Secretary and Director of Field Studies, New York Commission on
Ventilation, New York, N. Y.*

DURING the school year 1926-27, the Commission conducted a preliminary study into the effect of ventilation on the health of school children in three modern, steam heated, mechanically ventilated schools and in three old, furnace heated, naturally ventilated schools. The incidence and duration of diseases of the upper respiratory tracts of the pupils were taken as the criterion for judging the relative healthfulness of the two types of ventilation under consideration, but in actual practice in this preliminary study, in which the determination of the presence or absence of these diseases rested largely with the parents and teachers, the medical terminology was discarded and the diagnoses were interpreted under the general headings: colds or sore throats.

The crude results of this study support, in general, the findings of the Commission's studies in certain schools of New York City some ten years earlier.¹ The mechanically ventilated schools showed an excess of 47 per cent in total absenteeism; of 67 per cent in absenteeism due to respiratory illness; of 80 per cent in respiratory illness among the pupils present, and of 77 per cent in the total of respiratory illness among pupils present and absent.

This apparently decisive confirmation of the Commission's earlier studies might be accepted as the final and definite answer to the question of the relative superiority of natural over mechanical systems of ventilation. But, just as it has been so frequently shown that *crude* death rates are not reliable indices of the relative healthfulness of two communities, so it may be shown that in these schools the *crude* rates of total absenteeism and that part of it due to respiratory illness are not to be relied upon as an infallible guide in determining which of two types of ventilation is the more healthful—and the reasons in the two cases are much the same!

* Abstract of report, delivered before the American Society of Heating and Ventilating Engineers at their Annual Meeting, January 24, 1928. The complete report under the title of "Effect of Ventilation on the Health of School Children," will be published in the *Journal of the American Society of Heating and Ventilating Engineers*, April, 1928.

Communities differ in the age, sex and racial compositions of their populations, and school populations differ in the same manner. It is only after mortality rates are corrected for residence and the differences of age and sex are compensated by "standardization" or adjustment to a standard population, that one may safely take even the first steps in deciding which of two communities is the more healthful. Furthermore, judgment should not rest on the experience of a single year. The same precautions hold in the judgment of the healthfulness of methods of school ventilation.

Certain characteristics of the populations of the six schools included in this preliminary study are shown in Table I.

TABLE I
CHARACTERISTICS OF SCHOOL POPULATIONS

School	Grades	No. of Pupils	Percentage of Pupils of American Parentage	Average Age of Pupils (Years)	Percentage Males
<i>Mechanically Ventilated Schools</i>					
Salem Hyde	2-5	146	91.8	8.3	56.2
Seymour	2-8	707	62.0	11.1	50.6
Danforth	2-6	379	85.5	9.5	47.8
Totals		1232	72.7	10.3	50.4
<i>Naturally Ventilated Schools</i>					
Montgomery	2-6	325	65.0	9.9	50.5
Merrick	2-6	232	91.4	8.9	51.3
Townsend	2-3	237	4.6	8.2	53.2
Totals		794	54.6	9.1	51.5

The mean temperature of the air in the classrooms and the attendance and health records of the different schools are given in Table II.

TABLE II
MEAN TEMPERATURES, ATTENDANCE AND HEALTH RECORDS

School	Mean Temp. (°F)	Total* Absences	Absences Due to Resp. Ill.*	Resp. Dis. Among Pupils Present*	Total Respiratory Disease*
<i>Mechanically Ventilated Schools</i>					
Salem Hyde	70.2	6.4	3.4	20.4	23.8
Seymour	70.1	7.7	2.6	13.6	16.2
Danforth	69.5	6.7	3.5	6.9	10.4
Totals	70.0	7.2	3.0	12.6	15.6
<i>Naturally Ventilated Schools</i>					
Montgomery	71.7	6.5	2.0	9.1	11.1
Merrick	68.3	4.1	2.4	6.0	8.4
Townsend	65.8	3.7	1.0	5.4	6.4
Totals	68.5	4.9	1.8	7.0	8.8

* Per cent of Total Pupil Sessions.

The superiority of natural ventilation *appears* clearly established by the average of the gross attendance and health records presented in Table II. All the naturally ventilated schools show lower rates of respiratory illness absenteeism than any of the mechanically ventilated schools, but with groups of various racial compositions, the attendance

figures must be studied in this connection to see if these differences have any bearing on the results.

It is interesting, if not significant, to note that the naturally ventilated Townsend School, attended by pupils of whom 95 per cent are of Italian origin, had the lowest average temperature and at the same time the lowest rates of total absences, respiratory illness absences, and respiratory illness among the pupils present. The naturally ventilated Merrick School, with a population containing but 10 per cent of pupils of foreign parentage, and having the next lowest average temperature of the six schools, ranked second in total absenteeism, in respiratory illness among the pupils present and in total respiratory illness, and third in absenteeism due to respiratory illness. On the other hand, the naturally ventilated Montgomery School, which had the highest average temperature of the six schools, attended by pupils of whom 35 per cent were of foreign parentage, while ranking fourth in total absenteeism, in total respiratory illness and in respiratory illness among the pupils present, held second place in absenteeism due to respiratory illness.

The first step in the analysis of these data is the examination of the race stock of the pupils and of the ratios of respiratory illness absenteeism to total absenteeism and to total respiratory illness.

TABLE III
PERCENTAGE OF PUPILS OF AMERICAN PARENTAGE
PROPORTION OF ABSENTEEISM DUE TO RESPIRATORY ILLNESS
AND
PROPORTION OF CASES OF RESPIRATORY ILLNESS
ATTENDING SCHOOL

School	Percent Pupils of American Parentage	Ratio R. I. Absenteeism to Total Absenteeism	Ratio R. I. Among Pupils Present to Total Resp. Illness
<i>Mechanically Ventilated Schools</i>			
Salem Hyde	91.8	53%	85.5%
Seymour	62.0	33%	84.0%
Danforth	85.5	53%	66.4%
Totals	72.7	41%	80.0%
<i>Naturally Ventilated Schools</i>			
Montgomery	65.0	31%	82.0%
Merrick	91.4	59%	71.5%
Townsend	4.6	28%	84.4%
Totals	54.6	37%	79.6%

Again, as far as averages are concerned, there is relatively little difference between the two groups, but examination of the second column of Table III for the individual schools shows that regardless of the type of ventilation, in those with the higher percentage of pupils of American parents, respiratory illness causes twice the absenteeism it does in the other schools. Likewise, the third column of figures supports the fact

that an American child with respiratory illness is much more likely to be kept at home than is the child of foreign parentage. A study of respiratory illness absenteeism by grades (not reported here) brings out the fact that the higher the grade the lower the incidence of respiratory illness.

Unless these factors of race and age can be compensated, one is not warranted in drawing the conclusion from the rates of respiratory illness absenteeism that one type of ventilation is more favorable than the other.

Such an adjustment may be effected with the elimination of the Salem Hyde and the Townsend Schools. These schools are widely separated and not in the same parts of the city as the other four schools. Further, the Townsend school is attended almost exclusively by pupils of Italian origin. Of the remaining 4 schools, Seymour (mechanical) and Montgomery (natural) are in the same neighborhood, and are attended by approximately the same type of pupil. The same observations hold for Danforth (mechanical) and Merrick (natural).

Restricting consideration to grades 2 to 6 in these 4 schools, we have groups of the following characteristics:

TABLE IV
CHARACTERISTICS OF PUPILS IN TWO MECHANICALLY VENTILATED AND TWO NATURALLY VENTILATED SCHOOLS IN WHICH EFFECTS OF RACE AND AGE ARE APPROXIMATELY BALANCED

	Mechanically Ventilated Schools	Naturally Ventilated Schools
Percentage Pupils of American Parentage	71.0%	76.0%
Average age of pupils (years)	10.0	9.5

In these groups, both the average age and the racial composition of the population are practically identical—very slightly in favor of the mechanically ventilated schools. Despite this fact, the naturally ventilated schools show the better attendance and health records as given in Table V.

TABLE V
CONSOLIDATED ATTENDANCE AND HEALTH RECORDS IN TWO MECHANICALLY VENTILATED AND TWO NATURALLY VENTILATED SCHOOLS IN WHICH THE EFFECTS OF RACE AND AGE ARE APPROXIMATELY BALANCED

	Mechanically Ventilated Schools*	Naturally Ventilated Schools*	Excesses in Mechanically Ventilated Schools
Total Absences	7.0	5.4	29%
Absences due to Respiratory Illness	2.9	2.2	32%
Respiratory Illness Among Pupils Present	8.8	7.8	13%
All Respiratory Illness	11.7	10.0	17%

* Per cent of total Pupil Sessions.

Even with this somewhat refined treatment of these data, the conclusion that natural ventilation of schools is the more healthful is hard-

ly warranted from this study. This warning is of particular importance in this instance in view of the fact that the experience covers but a single year, and, furthermore, the diagnoses of respiratory illness—the fundamental observations on which this preliminary study was based—originated on the one hand in the excuses for absence sent in by the parents of absentees, and, on the other, with the teacher in so far as the pupils in attendance are concerned. *No amount of mathematical refinement can overcome the handicaps of error in original observations.*

The study is being continued during the present school year, with school nurses, who have received special training, responsible for the determination of the existence of respiratory disease (where diagnosis has not been made by a physician), both among the absentees and the pupils in attendance. Although there is nothing to indicate that the methods of the preliminary study tended to favor one type of ventilation over another, restriction of the diagnosis to persons especially trained suggests itself as a more trustworthy foundation on which to base definite conclusions.

Health Education in India

IN the United Provinces the Red Cross coöperates with the Hygiene Publicity Bureau which carries on extensive health work. Workers are sent out to fairs, religious and social gatherings to give health talks and distribute literature. At a recent exhibition organized by the Public Health Department in Lucknow, the Red Cross and the Hygiene Publicity Bureau had a joint exhibit of models, posters, charts and lantern slides, the latter being arranged in upright frames illuminated from behind by electric bulbs. The other exhibits included smallpox, cholera, plague, malaria and tuberculosis sections, models of sanitary and insanitary villages, houses and wells, a model travelling dispensary such as is in actual use in rural districts and a sanitary engineering stand. Medical men were in charge of the different sections in order to explain the exhibits and give population health talks. In the evenings the film "Why Die of Cholera?" was shown to large audiences.

Special arrangements were made for school children to visit the Exhibition and questions on the subjects treated were afterwards set in school examinations. The Public Health Department also gave a prize for the best descriptive essay on the Exhibition.—*League of Red Cross Societies Bulletin*, Dec. 1, 1927.

The Vitamins as Factors in Health and in Food Values.*

YOUR committee is not unmindful of the fact that it reported under a title of similar purport only a few years ago;¹ but so rapid have been the advances of recent years—not so much in the pure chemistry of the vitamins as in our knowledge of their nutritional relationships, their significance to health, and their distribution among food materials—that a new attempt to summarize the outstanding characteristics of the vitamins as factors in health and in food values seems desirable from the point of view of 1927.

Our report of 5 years ago dealt with vitamins A, B, and C. The present report, or series of reports, must deal not only with the changes which the intervening years have wrought in our ideas regarding these substances, but with some other substances as well. The fat-soluble antirachitic substance is now generally grouped with the vitamins and is commonly designated as vitamin D. Another fat-soluble substance which, in addition to substances previously known, has recently been discovered as essential to reproduction is known as vitamin E. And still more recently there has been a rapid accumulation of evidence, which now in total seems quite conclusive, that what has hitherto been known as vitamin B involves at least two substances, both essential to growth. Since neither of these alone sufficiently fulfils the concept for which the term vitamin B has stood, it would seem unwise to reassign this familiar term to either of the substances which together it has hitherto covered, and much wiser to let "vitamin B" be spoken of as "vitamin B complex" so that the relation between designation and connotation shall not undergo any confusing change; and it is proposed² that the two fractions of the vitamin B complex which are at present clearly recognized be designated respectively as vitamins F and G. (These will be easily remembered because F will stand for the antineuritic substance so closely associated with the name of Funk; and G for the factor which Goldberger believes to be preventive of pellagra.)

Few new ideas in science have gained currency with the public so rapidly as has the idea of vitamins. Nor has it escaped commercial exploitation. Numerous preparations are being marketed through the

* Report of the Committee on Nutritional Problems presented to the Food and Drugs Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

drug trade at high prices under claim of containing one or more of the vitamins in relatively concentrated form. This is not the place to attempt the discussion of the merits of such preparations. In due time their standardization will doubtless receive the attention of the federal authorities charged with the administration of the Food and Drugs Act.

To us as a Committee on Nutritional Problems, it appears that, while the physician may occasionally desire to employ a vitamin concentrate, the public will find it much safer and more economical to obtain vitamins as normal constituents of a wisely chosen food supply than from the drug store, whether in the form of pills, powders or extracts, or at the soda fountain. Even should all such preparations be held to the complete fulfillment of their claims for vitamin values, it is plain that in order to yield the manufacturers a profit all such highly manipulated products must be sold at prices which make their vitamins cost more than when these vitamins are purchased in the form of foods. When the importance of the vitamins is fully recognized and given due weight in the planning of food supplies, there will probably be but rare occasion for the purchase of vitamins in any other form than that of staple foods.

We wish to emphasize, however, the need for full recognition of the importance of conserving the natural vitamin values of foods to the fullest possible extent; and of frankly acknowledging that every diminution of vitamin content is a diminution of food value. Up to the present we have, perhaps, been too complacent on this point, tending sometimes to evade serious consideration of it on the ground that "we will probably get enough of the vitamin in our liberal mixed diet anyway." But we do not ignore the abstraction of a part of the cream from market milk on the ground that the partially skimmed milk is still an excellent food and that our mixed diet would probably furnish us enough fat anyway; we recognize that to whatever extent the milk-fat with its vitamin A is diminished, to that extent the food value is lowered. So we should recognize with equal clarity and frankness that when much of the vitamin B of wheat or rice is removed in milling, or much of the vitamin C of cabbage or spinach is lost in cooking or canning, to that extent there is a diminution of food value, however excellent the resulting product may be, and however likely that at least our minimum requirements for vitamins will be met.

Especially should this be emphasized in view of the fact that recent investigations tend strongly to the view that "enough" is an ambiguous term as applied to our vitamin intake, because the optimum (the amount that we can use with greatest advantage to our health) is apparently manyfold greater than the amount which we must have

to protect us from deficiency disease. Of total food (calories) we can advantageously use only a little more than we actually need, for the surplus, stored as fat, would soon render us too stout; of protein no large surplus can be stored and an intake more than double the actual requirement is rightly regarded as a possible source of danger; but in recent experiments with vitamins, intakes of several-fold the amounts demonstrably needed have shown no danger but on the contrary have proved distinctly advantageous. Hence, while for some factors of food value and nutritive requirement the optimal intake is only a little above the actual need, with the vitamins the case appears to be different and more like that of fresh air—we can exist without conspicuous injury on relatively little, but we can use advantageously a manyfold larger allowance, generally as much as we can conveniently get.

VITAMIN A

It seems unnecessary to recall here the story of the simultaneous discovery and early investigation of vitamin A by McCollum and Davis¹ and by Osborne and Mendel² or to rehearse the abundant evidence that a shortage of vitamin A in the food, results, sooner or later, in a widespread weakening of the tissues and functions of the body. Wolbach and Howe,³ among others, emphasize the fact that in addition to the well known eye trouble, shortage of vitamin A causes many other pathological changes. These include the presence of abscess-like cavities filled with yellow cheesy-like material at the base of the tongue, in the pharynx, and in the submaxillary glands. They find that the cavities are cysts lined with a stratified keratinizing epithelium and the cheesy mass of mixture of desquamated keratinized cells and leucocytes. Microscopic study of the lesions in rats killed at progressive stages of vitamin A deficiency has shown that the principal change is "transformation of various epithelia into a stratified squamous keratinizing epithelium. This change is practically constant in the upper respiratory tract, including the whole of the nasal passages, larynx, trachea, and bronchi." Similar pathological changes are found widely distributed elsewhere in the body also. Because so many of our staple foods are so poor in vitamin A and because a shortage of this substance weakens the body in so many ways and increases its susceptibility to so many infections, it appears probable that differences of intake of this vitamin, more than of any other, affect the general health and length of life of the people of today—and this through such differences in food habits as are so familiar as to be regarded with indifference.

The experimental evidence suggests that vitamin A probably plays

in the body the double rôle of a tissue constituent and also of a "regulatory" substance concerned with the maintenance of normal conditions and the control of nutritional processes.

Several investigators have emphasized the fact that respiratory disease is more frequent among experimental animals whose food is relatively poor in vitamin A, and it has also been found by careful experimental investigation that in such cases there is also an actual diminution of the vitamin A content of the lung tissue. Conversely, a liberal intake of vitamin A leads to increased resistance, a higher vitamin A content of lung tissue, and an increased storage of this vitamin in the liver. Muscle tissue contains but little vitamin A in any case.

Recent investigation has strongly emphasized both the extent to which the body can store vitamin A, chiefly in the liver, and the great importance of such a reserve store of this vitamin to the life and health of the individual. In a carefully conducted series of experiments upon laboratory animals, vitamin A was fed up to about 80 times as much as is usually considered necessary for adequate nutrition and even this high level of intake was found advantageous through increasing the amount stored. In these experiments with rats, the body usually had acquired its maximum reserve store of vitamin A at about the time that the growth was completed; but by liberal feeding with food rich in this vitamin it was possible to build up in a younger animal a larger store than the maximum ever acquired by the animal of less fortunate nutritional history.

Since the storage of vitamin A in the body has thus been shown to be so important, it becomes plainly a wise economy to invest rather freely in this factor of food value in order that the body may be adequately insured in this respect.

In the light of this newer knowledge regarding the extent and significance of the storage of vitamin A in the body, it becomes probable that the supposed lesser need for this vitamin by the adult than by the young is apparent rather than real, and is largely attributable to the facts: (1) that the development of the adult has carried him beyond the point at which a deficiency becomes quickly manifest in any such apparent sign as the cessation of growth; and (2) that the adult has presumably had more opportunity to provide himself with a bodily store of this vitamin which then carries him over periods of deficient intake.

That vitamin A plays an extremely important part in the nutrition not only of the young but also of the adult is now well established.

Sherman and MacLeod⁷ have described experiments in which

parallel groups of rats of identical previous history were fed upon two types of diet, one rather low and the other fairly high in vitamin A, from soon after weaning-time until natural death. The smaller amount of vitamin A proved sufficient for normal growth up to nearly normal adult size, but not for successful reproduction, and rarely did it support satisfactory longevity. The parallel animals receiving the more liberal allowance of vitamin A grew to fully average adult size; were successful in reproduction and the rearing of young; and lived on the average a little over twice as long as those on the diet equally good in all other respects, but lower in vitamin A.

These experiments show strikingly that a proportion of vitamin A in the food, sufficient to support normal growth and maintain every appearance of good health for a long time at least, may still be insufficient to meet the added nutritive demands of successful reproduction and lactation.

Along with the failure to reproduce successfully there usually also appeared in early adult life an increased susceptibility to infection, and particularly a tendency to break down with lung disease at an age corresponding to that at which pulmonary tuberculosis so often develops in young men and women.

The bacillus involved is different; but the close parallelism of increased susceptibility of the lung to infection at this stage of the life history appears very significant, especially in view of the fact^{*} that the vitamin A content of lung tissue varies with that of the food.

Especially noteworthy was the repeated observation of young females growing normally and presenting every appearance of good health throughout youth on a diet low in vitamin A but failing utterly to succeed in the rearing of a second generation, and showing a strong tendency to break down in health at an age at which they should have been in the prime of life.

Thus it is clearly shown that vitamin A is an even more important factor in health and in food values than has previously been appreciated, for it must be supplied in liberal amounts not only during growth but in the food of the adult as well, if a good condition of nutrition and a high degree of individual and community health and vigor are to be maintained.

In view of the manifest importance of such quantitative differences in vitamin A intake as may readily occur among people living upon diets regarded as normal, methods for the measurement of the relative amounts of this vitamin in different foods have been developed and the more quantitative our information becomes, the more we are

impressed with the extremely wide differences among foods with respect to their vitamin A values.

Vitamin A is formed in the green leaves of plants and in general these are much richer in this vitamin than are other organs of the plant. The pale inner leaves of headed lettuce and cabbage are not nearly so rich as are the green outer leaves; and recent careful work has shown that the green plant tissues other than leaves which we use as food in the form of string beans and green peppers, are, like the green leaves, rich in vitamin A.

Animals obtain their supplies of this vitamin from plants, either directly or through other animals. Vitamin A can be stored in the animal body as already noted. This storage occurs mainly in the liver; but significant amounts may also be stored in adipose tissue, depending upon the food of the animal and the rapidity of fattening. Muscle tissue contains very little vitamin A, even when the food has furnished it in abundance. The amount in the glandular organs is variable depending upon how the animal has been fed. Eggs and milk are more important and constant sources of vitamin A than are any of the body tissues.

It is chiefly because of their outstanding importance as sources of vitamin A, as well as of calcium, that McCollum has designated milk and the green vegetables as the "protective foods." In view of the foregoing it seems advisable to repeat the recommendation made by the committee in its report of last year, namely, to emphasize the importance of including milk in the daily diet to the extent of at least a quart for every child and not less than a pint for the adult.

Space does not permit any detailed discussion here of the stability of vitamin A; but, in brief, it may be said that this vitamin is sufficiently stable under all the conditions commonly encountered in the industrial and household manipulations of the foods which chiefly furnish it, so that foods of the kinds indicated as good sources may usually be counted upon to retain their value in this respect as they appear upon the dining table. The recent work of Miller² shows that heating at reduced acidity or slight alkalinity (about pH 9) which is very destructive to vitamins B and C, has little effect upon vitamin A.

In view of the limited time allowed for each communication at these meetings, and the fact that committee reports should be published in the same form in which they are presented and accepted, it is impracticable to discuss the other vitamins in the present paper. If the section desires, we shall be glad to report in similar manner upon other vitamins at a subsequent meeting or meetings.

The Parker Bill Is Passed

THE Parker Bill for the coördination of the public health activities of the federal government was passed by the House of Representatives on March 7, 1928. This measure, H. R. 11026, is in somewhat revised form, as the original first section, which would have given the President power to transfer to the U. S. Public Health Service bureaus carrying on health work, was deleted, and the second section was changed, so that scientific personnel of the U. S. Public Health Service would be detailed to other bureaus not by order of the President, but only at the request of an executive department.

The remainder of the bill is the same, and contains important provisions for increasing the scope of the Hygienic Laboratory, giving a commissioned status to sanitary engineers and other non-medical scientists, the creation of a nurse corps, establishment of a national advisory health council, and the detail of scientific personnel to educational and research institutions.

Before this bill can become a law it must be adopted by the Senate and signed by the President. A companion measure, S. 3356, has been introduced in the Senate by the Honorable Wesley L. Jones of Washington and has been referred to the Committee on Commerce of which Mr. Jones is chairman. In spite of the emasculation of the first two sections, the bill still is of vast importance to national health, and sanitarians should now communicate with their senators and urge their support for the Jones bill for federal health coördination.

Time and Cost Study Problems*

AN analysis of the problems of the time and cost in nursing involves the following points:

Does the present method of computing costs, with the visit as the unit, satisfy our needs?

If not, would it be of benefit to establish a cost based on time, but translated into time by each type of visit?

Is it practicable to work toward a specification form for content of visit?

How will the charge item be adjusted?

Is it not worth while for each visiting nurse service to study the situation further?

Referring to the first item it was pointed out that the causes for variations in costs per visit have been ignored. Too, in trying to reach comparable figures there has been an effort to reach the same number of visits for each organization. This leads to a speeding-up process which is a decidedly poor method of obtaining good work from a staff.

The nursing day is divided into travel, record keeping, field work, conferences and hours devoted to staff education.

We are already putting into practice many suggested schemes for decreasing travel and record time, and thus releasing time for field activities.

The fact that the visiting nurse is the logical agent to disseminate health education for disease prevention was emphasized in the report. In order to discharge her duties in a most satisfactory way it is necessary for her to acquaint herself with most recent facts, for instance in the fields of nutrition and mental hygiene, and to confer with experts about her special case problems.

Time is needed. If time is allowed, then visits go down and costs go up, and by following our present methods of computation, the very things we want for the promotion of community health are forbidden us because they make our cost prohibitive.

After further analysis of this point it was suggested that nursing organizations adopt "the average time per type of visit as the cost unit," and "instead of stating our charge on the basis of time, the visiting nurse service can quote its rates to the patient on the basis of type of work done."

If our nursing is figured on basis of time spent, the acute nursing costs will be properly allocated and the increased charge for these services will permit us the opportunity we want for the educational and preventive program.

* Abstract of a paper, *Time and Cost Study Problems*, by Marguerite A. Wales, R.N., General Director, and Mabel C. DeBonneval, Statistician, Henry Street Visiting Nurse Service, New York, N. Y., read before the Public Health Nursing Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

The complete paper will appear in the March, 1928, issue of the *Public Health Nurse*.

Another reason given for the adoption of the time unit figure of cost was that it would direct attention to the quality of work and to the content of the visit.

Since the American Public Health Association is working toward specification of content of service, might it not be well to institute an appraisal form of our nursing visit content. There would be one form for the ante-partum visit, one for the post-partum, etc., and by an inspection of the form as related to each organization's work we could readily account for the time spent in the visit. It will indeed be necessary to adopt some such method, because if we use only the time unit and we come to a comparison of similar services in communities, we have no way of arriving at any standard of time.

An analysis must be made of the division of time given over to the various services and the nursing organizations must be cognizant of the health needs of the community.

An ever present source of concern is that the fear that the cost of visiting nursing will become a prohibitive item. Any growth in the welfare program means a corresponding increase in the average per visit cost, so that the net result is a lessening of the fee charged for contract acute work. Until the associations have studied their visits we cannot say what the result of this change of basis of charge would be.

Disposal of Sewage and Industrial Wastes

Definitions of Terms*

Mr. John F. Skinner, Chairman,
Committee on Disposal of Sewage and Industrial Wastes,
Public Health Engineering Section, A. P. H. A.

Dear Sir:

I hereby present the following report on Definitions of Terms Used in Sewerage and Sewage Disposal Practice.

In 1915 the Committee on Sewerage and Sewage Disposal of the American Public Health Association, George S. Webster, Chairman, undertook the preparation of "Definitions of Terms Used in Sewerage and Sewage Disposal Practice," and at the Annual Meeting held in October, 1917, after considerable study, involving the replies to questionnaires and a large amount of correspondence and discussion, the committee presented its report. This was printed in the October, 1917, JOURNAL but was never brought up for official approval. Meanwhile sewage disposal especially was being developed along new lines and by 1923 it was felt desirable that the entire subject should be reviewed and the definitions brought up to date and formally adopted by the Association. A new committee was thereupon appointed with Mr. John F. Skinner, Chairman.

* The Definitions of Terms Used in Sewage Disposal Practice, which is the Report of the Joint Committee of the A. P. H. A. and the A. S. C. E., will be published as a manual by the A. S. C. E. Members of the Public Health Engineering Section of the A. P. H. A. will receive copies. See *A. J. P. H.*, Feb., 1927, p. 199 for report of committee.

Meanwhile the subject had received attention from the Sanitary Engineering Division of the American Society of Civil Engineers, who appointed a similar committee with the late Prof. George C. Whipple as Chairman. At the Annual Meeting in 1924, on the receipt of the report of Mr. Skinner's committee a Resolution was passed by the Sanitary Engineering Section of the Association providing for coöperation between the two committees in the preparation of a joint report. This Joint Committee submitted a Questionnaire which brought out a large number of suggestions. These were to a considerable extent canvassed and tabulated when it was decided to turn over all the material and results reached at that time to the undersigned to prepare a final draft. This draft would then be submitted to each of the two organizations interested for approval.

As there were a number of definitions concerning which there remained a decided difference of opinion, these were submitted to ten engineers of prominence in sanitary engineering, who had not it is believed, with one exception, served on past committees devoted to the subject. The answers received, together with a number of valuable suggestions offered voluntarily by others, served to clarify the debatable points to such an extent that the entire list could be put in shape for presentation.

Owing to the extended and conscientious study given to this matter and the care taken to meet the views of those whose judgment was believed to carry particular weight in these special lines of technology, it is hoped that the final list as now submitted may meet the approval both of the American Public Health Association and the American Society of Civil Engineers.

In both the theory and technic of sewerage and sewage treatment we are making a steady advance. Especially is the matter of treatment undergoing a process of evolution. Under these conditions some terms now in use may become obsolete or modified in meaning while new terms will come into common use. For this reason no set of definitions can be said to be adequate and proper for all time but should be subject to a periodical revision, say once a decade, and it is with this reservation that the definitions are herewith submitted for approval.

KENNETH ALLEN

First Maternity and Infant Health Center in Milan

IN compliance with the provisions of the Italian maternity and infancy welfare law of 1925 the first maternity and infant health center was recently established in Milan. The purpose of this health center is the promotion of maternal and infant health rather than the treatment of physical defects. Several organizations, among them the Maternity Insurance Fund of Italy, and the Italian Infant Welfare Union, one an official, the other a private organization, coöperate in the management of the center. The center is equipped according to modern hygiene standards and the work is done by a trained staff. A woman graduate in puericulture will soon be appointed as home visitor to replace the volunteers now connected with the center.—*La Pediatria*, Naples, Nov. 1, 1927, p. xix.

POMONA'S HEALTH CENTER

The Pomona Health Center, recently opened to serve the citizens of Pomona, California, was erected by Los Angeles County at a cost of \$68,000. The site was given by the City of Pomona and the institution is located adjacent to the other municipal buildings in the civic center. It is considered one of the most adequately appointed and modern health centers in the country. The center is equipped and staffed to give service and treatment to those seeking it.

EDITORIAL SECTION

Expressions of opinion and statements of supposed facts are published on authority of the writer under whose name they appear, and are not to be regarded as expressing the views of the American Public Health Association, unless such statements or opinions have been adopted by vote of the Association.

OF WHAT USE ARE OUR HEALTH OFFICIALS?

IT is worth while to consider the answer to this question. It will give faith, courage and hope to our health officers. It will remind a generation passing off the stage of terrors well-nigh forgotten, and it may lead many others, complacent in our 20th century environment, to a fuller appreciation of the riches of health that have been won with so much toil.

Fear is the genesis of the health officer. American public health is built on a foundation of epidemics. In the mid-19th century no city was free from the fear of yellow fever, smallpox, cholera and the dreaded ship fever brought in by our hordes of immigrants. Typhoid fever, just differentiated from typhus, was reaping a harvest in our growing cities. Scarlet fever, then a virulent disease, appearing in waves, was the great terror of mothers until a worse came in the form of diphtheria in the late 50's. In the early years, special boards, or committees, were organized by communities to cope with the outbreak after it was upon them, and they did splendid work, though often ineffective because too late. Far-seeing citizens began to realize that, as in fighting fire, so in fighting disease, it is necessary to be ready at the first alarm. The emergency boards of health became permanent and there has thus gradually grown up our organized public health service, national, state and local.

The terror inspired by the great epidemics of the 19th century has vanished. Even the health workers have forgotten that cholera once caused a death rate of 140 per 100,000 population in New Orleans and stopped all business in New York; that yellow fever brought commerce to a standstill and depopulated large cities; that typhoid fever caused a mortality in one year in Chicago of 175 per 100,000 population; and that diphtheria death rates of over 300 were not unknown. In the 70's of the 19th century, as on many previous occasions, smallpox ravaged our cities and towns, paralyzing business, and wasting millions of

dollars. That things are better now is due almost entirely to official health work. There were then no foundations to combat cholera, no typhoid fever associations, no anti-smallpox societies; though there was an organization of anti-vaccinationists to hamper the health officers in their work.

Just as rapidly as science has shown the way, official health workers have followed. It is true that scarlet fever and diphtheria still prevail, but do not kill as formerly. If Chapin's theory is correct, the isolation of the severe strains of scarlet fever has been an important factor in making the deaths negligible. So, too, the phenomenal decrease in diphtheria mortality is due, in large measure, to the efforts of health officials in encouraging the use of antitoxin and in securing the immunization of children. Of all the great epidemics, influenza is the only one against which science has failed to furnish health officers with effective weapons.

In the warfare against infectious diseases, official health agencies employ means which cannot be used so effectively by other agencies, if used at all. Thus the control of the environment is naturally a municipal or state function. State and local health officers have shown the need for the protection of water supplies and have indicated how this may be secured. They have shown the necessity for proper excreta disposal, not only for cities and villages, but for every farm in the land. Health officers have never feared to urge public improvements necessary for the public health, even when opposed by politicians, the press and powerful commercial interests. It is almost entirely due to such efforts that typhoid fever is a vanishing disease. It is because municipal health officers have banished *Aedes aegypti* from our cities that yellow fever is extinct. Malaria and hookworm disease can be controlled by controlling the environment, and progress is dependent upon local official county health organization.

Though the isolation of contagious diseases is not the panacea it was at one time thought to be, it is still indispensable and must necessarily be enforced by state or local officials. Of greater importance is immunization. Long experience has shown that, if left to their own devices, comparatively few will avail themselves of the benefits of this method of protection against smallpox, typhoid fever, diphtheria, rabies, or other diseases. Only the health officer has the interest to push this practice to an extent to secure worth while results and, even in the presence of virulent smallpox, he finds it difficult enough. Until recently other agencies have done little.

Though the importance of pure food to good health has been much exaggerated, it is necessary that a fairly strict supervision be kept. This is especially true of milk. The public and the medical profession

would be greatly disturbed, and not a little harm would result, if we should revert to the *laissez faire* practice of half a century ago.

Another great thing which the health officer has accomplished for the public and for the medical profession is the establishment and popularizing of the diagnostic laboratory. The first of these laboratories was set up in the health department of New York City and fortunate it is that other city and state departments so rapidly followed suit.

An allied health department activity is the distribution and in some instances the production of biological products. Again New York City showed the way by distributing and by making known the value of diphtheria antitoxin. When one sees the number of physicians who now fail to use this remedy, one wonders what the loss of child life would have been if health officials during all these years had not constantly preached to the public, and to the doctors, the value of this remedy. They find it necessary to continue the preaching even now.

With the control of the old time epidemics, health officers did not rest on their oars. The advancement of medical science has been continually developing new methods for fighting disease and promoting health. Many new and unofficial agencies have come to the aid of official health officers and have done much to stimulate the less energetic and the poorly equipped among them. Not only have the old time epidemics disappeared, but the general death rate has been cut in two and phenomenal progress has been made in prolonging life and in reducing a number of specific death rates. Better economic conditions, better medical treatment, the entrance of many new agencies into health work, as well as other factors, have had a share in securing these results. Health officials, especially local health officers, have had an indispensable share in the great work.

The new health movement of the present century relies largely on education. For many of the agencies which are employing it so strenuously this is somewhat of a venture. So long, however, as there have been health officials, it has been one of their most important duties to educate their communities. Of late years they have been taking a leading part in this movement. Efficient health officers, if the politicians let them stay in office long enough to get acquainted with their constituents, wield an enormous influence and, through their bulletins, posters, lectures, newspaper articles and other means, perhaps accomplish more even than does more elaborate material from a distant source. Bundesen, just before his removal, got out some exceptionally fine literature, but the budget of most health officers does not permit them thus to vie with the great foundations.

Every health officer, whether medical or otherwise, realizes that the

scientific practice of medicine is the foundation of public health. State health officers have for years striven valiantly to improve medical licensure, to drive out the quacks and to fight nostrums. A great number of health officials, particularly local health officers, have done an immense amount of good by their bulletins, lectures, radio talks and newspaper articles in acquainting people with the achievements of medicine and in leading them to a firmer trust in scientifically educated physicians. The full-time health officer has a tremendous advantage in this, for the people believe that he has no ulterior motive. Perhaps the surest way to combat quackery is not by use of police power, but by the more positive and permanent method of leading the public to realize the worth of the well educated physician.

The 20th century public health movement is characterized by the development of unofficial agencies to combat specific diseases, or to promote personal health. To a far less extent than in the fight against epidemics, does this movement involve the exercise of police power and so is less dependent upon official action. Nevertheless, the antituberculosis campaign would be greatly handicapped if no control could be exercised over recalcitrant cases, if notification were not compulsory and if mortality and other data were not collected by official statisticians. It would be impossible to carry on the present fight against venereal diseases without the aid of the health officers. Though private agencies are doing much for the prevention of blindness, state and municipal health officers must be the ones to distribute prophylactics and to secure proper care of infected babies.

Though voluntary agencies have done splendid work in protecting the health of the infant and of the school child, the great burden of directing consultations, prenatal clinics, control of midwives, supervision of boarding farms and day nurseries and the medical supervision of school children falls upon health officers, sometimes in the health department and sometimes in the school department.

To an even greater extent, the campaigns against malaria and against hookworm infestation are made to center around the local health organization.

Then, too, the part played by official health workers in the development of voluntary organizations must not be forgotten. They have always been active promoters of the national, state and local associations.

The number of agencies actively engaged in promoting the public health is large. Perhaps their work sometimes overlaps, but there is room for all. Coördination and coöperation are necessary, and in the state, the city, the town and the country, the health officer, the legally constituted representative of the people, is the logical agent for bringing about this coördination, for it is he who works continuously, and

for the most part successfully, for this. It is impossible to conceive of health work as going on effectively in our thousands of communities except as centering around the health officer. Indeed it is a matter of common knowledge that health has improved to a greater extent in our cities with their well organized health departments than it has in rural districts, such a large proportion of which are still without an adequate public health service.

The Rockefeller Foundation is devoting its chief effort in the cause of public health to the development of local health organization and to improving its personnel. The U. S. Public Health Service, the State health departments and the insurance companies all believe that the local health executive must be the center of community health work. What is needed is not an increase in his powers, but protection against wicked political interference.

COMMON CAUSES OF ALLERGIC DISEASE

WHILE seldom dangerous to life, there are few things which cause greater discomfort than hypersensitiveness, the importance, as well as frequency of which has been so abundantly demonstrated during the last few years. Many cases of asthma, for example, which had made the sufferer practically hopeless of future usefulness, have been cured by very simple means. In spite of all that has been written, it is probable that the great majority of physicians are still not aware of the various substances met with in daily life which produce allergic disease.

Success in the treatment of these troubles depends upon the acuteness of the attending physician in connecting cause and effect. Biological houses carry long lists of substances with which one comes into daily contact, by the use of which the cause of the trouble is often easily diagnosticated through the skin test, and the cure is often easy. On the other hand, some very puzzling cases are met with. We recall one in which contact with silk in practically every stage of manufacture produced most alarming symptoms. In other cases the patient is found sensitive to a number of substances and then the doctor must rely upon his common sense and observation to connect exposure and the result of the skin test. A recent writer¹ has stated that this is generally due to our ignorance of, or disregard for, the relation between raw materials and the finished commodities with which one may come into frequent contact.

It is impossible to give here the complete list of substances in common use which may be the cause of allergic disturbance, but among them we must call attention to pillows, usually made of the feathers of some bird, or of different fleeces and animal hairs; mattresses, which

are usually made of some fiber or hair; blankets and rugs which are made of cotton, wool or some animal product; furniture which is upholstered with various fibers as well as animal fleeces; clothing made chiefly from cotton and animal fleeces; and furs, which are practically always animal fleeces, but very often mislabeled, and given some fancy name, which makes recognition difficult. The majority of furs are not purchased under their proper names. Most of them are clipped, sheared, dyed and otherwise manipulated to make them resemble more expensive products. There are a number of materials which contain no silk at all, but are sold under names suggesting that they contain or are made of silk.

In other cases where clean cotton, for example, is supposed to be the material used, practically all of the hull and dried seed will be found. Many materials made of cotton are sold under names suggesting that they are made in part or in whole of linen.

So the story goes, and the physician may be obliged to go through a large number of substances which are not even suggested by the names of those which he has reason to believe that the patient has come into contact with.

The partial or complete mislabeling of fibers used in the manufacture of domestic goods is extremely common. It is a matter over which the medical fraternity has no control, though it suffers from difficulties of diagnosis and treatment in consequence.

One might expect, in this day of the almost universal employment of cosmetics, that we would be able to add a number of these to the list, but orris root, which is very widely used, seems to be the only one which is frequently found at fault. It produces asthma, skin disturbances and hyperesthetic rhinitis. Almost all face and tooth powders contain orris root, and it is widely used in making perfumes. New names are being constantly invented, which further tax the ingenuity of the physician in making his diagnoses.

ASSOCIATION NEWS

COMMUNITY HEALTH AND HOSPITAL SURVEYS

THE attention of the members of the Association is invited to the following statement from a sub-committee of the Committee on Administrative Practice. The program as outlined has been developed by the Sub-Committee on Organized Care of the Sick, reviewed by the Executive Committee of the Committee on Administrative Practice and submitted to 564 state, county and local health officers to whom the *Health Officers' News Letter* is addressed, and is now submitted to the members of the Association at large for their information and for criticism and suggestions upon this tentative statement of policy of community surveys.

What restrictions or extensions upon the type of survey described in this statement do you believe should be laid down by a committee of your Association? Has your community a problem involving the facilities for organized care of the sick which such studies might help to solve?

C.-E. A. WENSLow, Dr.P.H., *Chairman,*
Committee on Administrative Practice

DURING the past year the Committee on Administrative Practice has been called upon to broaden the scope of its surveys and appraisals, having been requested in two cities, in which appraisals were asked for by the health officer, to include also studies of the hospitals and other organized facilities for the care of the sick. At the present time requests of similar scope are pending both from cities and several rural areas. It was decided last year by the committee to meet the requests, and on the basis of the experience gained, to determine thereafter the scope and policy appropriate to surveys conducted under the commit-

tee's auspices in the future. It is apparent that a real demand exists for a broader type of survey than had been conducted by the committee previous to 1927, and that facilities for the organized care of the sick are so closely related to the public health interests that the two should often be studied and considered together. On the other hand, it is obviously desirable for the American Public Health Association not to go beyond the field appropriate to a national association, whose primary interests lie in prevention rather than in curative work, or in individual medical practice.

For the purpose both of defining the problems that should be dealt with, and of guiding the scope and method of future surveys, a sub-Committee on the Organized Care of the Sick has been formed with the undersigned membership, representing various interests, in order to touch all the essential phases of the problem. Three members of the committee have been suggested informally by the president of the American Hospital Association.

The sub-committee, in several meetings and by correspondence has given careful consideration to the extent and limits which are appropriate to surveys under auspices of the Committee on Administrative Practice. The committee is prepared to consider requests and suggestions for surveys including hospitals, out-patient departments and other clinics, city physicians and other organized resources for the care of the sick.

The committee will not be concerned with studies of internal administration of hospitals or in the personal diagnostic or therapeutic care of patients by their physicians in hospitals or clinics, the planning and construction of their physical plants or the technical and educa-

tional standards involved in any of these institutions. It is intended that the Association carefully avoid entering fields in which such organizations as the American Medical Association, the American College of Surgeons and the American Hospital Association have primary interests and important existing activities.

Surveys within the proper scope of the committee will be regarded for the present as including such matters as the need for hospital beds, clinics or other organized curative facilities of a community; the social and economic groups for whom such facilities are needed; the geographical distribution and the interrelations of these facilities to one another and to other interests and agencies of the locality. Surveys of this type would ordinarily be conducted in connection with a study and appraisal of the official health department, the health work of the board of education and voluntary agencies (Visiting Nurse Association, tuberculosis association, etc.) requested by the health officer.

The sub-committee has been charged with the responsibility of supervising the

policies and methods of future studies involving the organized care of the sick. All future requests for surveys in which this is a factor will be carefully studied with the aim of defining the appropriate scope of the study and the elements of the local problem, to render each study as effective and as inexpensive as possible. The sub-committee has also in hand the preparation of suitable survey schedules.

The expense of surveys includes the actual cost of the field work, plus an allowance for expenses of the central office incurred in connection with the survey, including time of professional and clerical staff.

The committee regards this policy as tentative. It is entered into in response to apparent demand from the field itself.

ENUMERATION OF PUBLIC HEALTH WORKERS

THE Executive Board of the Association has authorized an enumeration of public health workers. Plans are now in process of preparation by a Committee on Census composed of John L. Rice, M.D., Health Commissioner, New Haven, Conn., Chairman; Prof. John F. Norton; Arthur E. Gorman; George Van Buren; Prof. C. E. Turner. The first task of this committee is to establish definitions and classifications. The committee met on February 10 and will meet again March 15.

CENTRAL PROGRAM COMMITTEE

AT the first meeting of the Central Program Committee, held on February 11, it was decided to begin the An-

nual Meeting program with the opening General Session on Monday evening, October 15, reserving the first day for committee meetings and meetings of related organizations. The program of the sessions will begin on Tuesday morning and continue through until Friday afternoon. The General Sessions will also be held on Wednesday and Thursday evenings, one of these sessions probably being a banquet.

The section programs are rapidly taking shape and plans are under way for joint sessions between the Health Officers and Public Health Nursing and Child Hygiene Sections; the Laboratory Section with the Food, Drugs and Nutrition Section and with the Public Health Engineering Section. The Laboratory Section will also have a joint session

with the Child Hygiene and Industrial Hygiene Sections on the subject of ventilation. Some of the sessions of the Child Hygiene Section will be held jointly with the American Child Health Association, which will hold its Annual Meeting at the same time.

All sessions will be held at the Hotel Stevens. The usual technical exhibit will be held in the exhibition hall at this hotel and space is being rapidly reserved by the leading manufacturers of scientific equipment and health products.

AWARD FOR PUBLIC HEALTH WORK

RHODE Island has won the prize for the year 1927 offered by the General Federation of Women's Clubs for having the highest percentage of local clubs engaged in public health activities. The award is one month's service of one per-

son engaged in making a survey of a particular community. Warwick, R. I., was selected by Dr. B. U. Richards, State Commissioner of Health, as the community to receive this service. The field work will be rendered by James Wallace, M.D., Associate Field Director, Committee on Administrative Practice, American Public Health Association, and Lucy Oppen, Staff Associate, Division of Health Education, American Child Health Association. The report of this survey will be published by the Metropolitan Life Insurance Company.

POCKET MEMBERSHIP CARDS

ATTRACTIVE yellow pocket cards have been prepared to be sent to all members and Fellows of the Association, who are in good standing with their Association. They will be mailed April 1.

NEW MEMBERS

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Diphtheria Death at Auburn—On January 9, Auburn experienced its first death from diphtheria since March 9, 1924. The victim was a 6 year old child who, according to the report received by the State Health Department, had not been immunized against diphtheria with toxin-antitoxin. A physician was not called early in the disease, and the antitoxin was not given until 2 days after the first call. Two younger children in the family were given protective doses of antitoxin, but two older ones who had been immunized some time before with toxin-antitoxin were not given any. All four remained well.—*Health News*, New York State Department of Health: V:13 (Jan. 23), 1928.

Potency of Toxin-Antitoxin—In spite of the practice of giving 3 doses of toxin-antitoxin to all new nurses at the Cook County Hospital there occurred during the period of approximately 18 months from January, 1926, to July 8, 1927, 29 cases of diphtheria. Of this number 10 nurses had had not less than 3 doses of toxin-antitoxin within 2 years and prior to 3 months before onset. Four nurses had received 3 doses of toxin-antitoxin within 3 months of time of onset. Twelve gave a history of having had no toxin-antitoxin or previous diphtheria. In 3 instances no data were available. It will be observed that there were 12 cases among those who had not had toxin-antitoxin, and 14 cases among those who gave a history of having had some toxin-antitoxin. The unprotected group consisted of 175 individuals, and the protected group included only 64. It is, therefore, evident that the percentage of those who contracted diphtheria was

greater in the protected than in the unprotected.

These facts led to the inauguration of tests for potency of the toxin-antitoxin preparation. Wide variations were found in the potency of commercial preparations now on the market, and in some instances there was even considerable difference among the lots made by the same manufacturer. The method used to determine potency was that adopted by the Hygienic Laboratory of the U. S. Public Health Service. The author recommends that when large numbers of toxin-antitoxin immunizations are to be done, it is advisable to make tests for potency on the particular lot of toxin-antitoxin to be used before work is undertaken.—Paul S. Rhoads, Commercial Preparations of Diphtheria Toxin-Antitoxin, *J. A. M. A.*, 90:254 (Jan. 28), 1928.

Record Forms—The Committee on Administrative Practice of the American Public Health Association has published for experimental use, 4 sets of record forms. These are for communicable diseases, laboratory, school medical inspection, and public health nursing. The nursing forms have been worked out by the National Organization for Public Health Nursing. In designing these forms the committee had in mind not only the desirability of keeping adequate records which would serve local needs and assist the health officer of the smaller community who feels the need of rigid economy, but which would, likewise, enable the administrator to accumulate figures which are essential to the application of the *Appraisal Form* as a measuring stick of the effectiveness of the communal health program.

The fact is appreciated that it will be quite impossible for a single suggested system of record keeping to be applied universally. Lack of uniformity in the laws of the various states, and in the activities and methods followed by health departments in the reporting and supervision of cases of communicable disease makes this impracticable. There should, however, be a record of all immunization treatments for diphtheria, typhoid fever, smallpox, etc.; epidemiological records for securing and preserving the essential facts regarding the major communicable diseases which have been reported and entry made on a suitable report card. In smaller cities and towns these are the only communicable disease records needed for the diseases of major importance. In the larger cities there should be added as a minimum a case record card, inspector's or placarder's record, nurse's record, and a summary record.

The various types of record forms used in public health laboratories may be conveniently listed under the following heads:

1. Accession Sheet, for recording the receipt of specimens in the laboratory
2. Identification Slip, for physicians or others submitting specimens
3. Examination Record, for an exact statement of all work performed on each specimen together with the result of such examinations
4. Report Form, for written reports
5. Summary Sheet, for showing the amount and kind of work done in the laboratory
6. Miscellaneous Record Slips, for convenience of the laboratory in keeping departmental records, record of parts of work, etc.

A form for recording health facts about individual school children over a period of years is also presented. It is prepared for schools in which the teacher has no professional assistance in caring for the health of her pupils. It is not meant to offer an alternative or a substitute to

professional health science. The purpose is to meet the situation in the best manner that is possible under existing circumstances wherein the teacher, for the most part, has no professional assistance. The committee feels that there are 4 main series of facts which should prove useful: (1) record of communicable diseases experienced, (2) record of immunization, (3) record of obvious physical defects, and (4) record of absences by cause.

The public health nursing record system includes:

1. Index Card
2. Family Folder
3. Maternity Service
4. Health Supervision Service
5. Morbidity Service
6. Extra Data
7. Nurse's Daily Report
8. School Service

The committee's report will be found in a publication of the Association consisting of 106 pages. Copies can be secured from the Association office at the rate of fifty cents each.

Cincinnati Goiter Resurvey—During the 1923-1924 school session a thyroid survey was made of 47,493 children in the elementary schools of Cincinnati. The first survey included 23,710 boys of whom 26.6 per cent showed thyroid enlargements, and 23,783 girls among whom 39.8 per cent showed thyroid enlargements. In 1927 the resurvey included 12,722 boys and 12,818 girls. In the resurvey the percentage of thyroid enlargements among the boys was 22.5. and among the girls 39.3. In general it may be said that the resurvey included the same children who were examined in 1923-1924. The author concludes that there is a lessened incidence of the disease and a considerable reduction in the number of goiters of moderate and marked degree, although the aggregate incidence of endemic goiter in 1927 was only slightly less than in 1924. It is

believed that iodized salt was a factor in the slight reduction of goiter, and other prophylactics may have exerted a favorable influence.—Robert Olesen, A Resurvey of Endemic Thyroid Enlargement in Cincinnati; *Pub. Health Rep.*, 43: 1113 (Jan. 20), 1928.

Measles In Institutions—Deaths from measles in institutions for children and for mental defectives have been responsible for from 3 to 26 per cent of the annual mortality from this cause in New York State, exclusive of New York City.

The average for the 8 years 1915–1922 was 10 per cent. Outbreaks accompanied by a large number of deaths have occurred only in institutions caring for children under 2 years of age and in

institutions for mental defectives. The author describes in detail the restrictive measures employed for the prevention and control of measles in institutions during the year 1923, there being 45 distinct outbreaks in 40 institutions with a total of 945 cases and 51 deaths. He concludes that convalescent serum will favorably influence the mortality if administered during incubation period, but admits that its use in the institutions was a decided disappointment. Delayed notification and difficulty in transportation detracted materially from its practical value as well as the difficulty of maintaining a reserve supply sufficient to meet the needs of a large institution.—Edward S. Godfrey, Jr., Measles in Institutions for Children, *J. Prev. Med.*, 2:1 (Jan.), 1928.

LABORATORY

C. C. YOUNG

DELETERIOUS EFFECTS FROM SERUM INJECTIONS

W. H. PARK, M.D., FELLOW A. P. H. A.

Director, Department of Health Laboratories, New York, N. Y.

BEFORE considering these effects individually it will be well to review briefly our present knowledge as to the reason of the development of the reactions in susceptible individuals.

Hypersensitiveness in man may be observed after both the enteral and parenteral introduction of many and varied substances. These inducing substances may be divided into two groups, antigenic and non-antigenic, viz: those which stimulate and those which do not stimulate the production of demonstrable antibodies. The degree of response to such substances is largely personal idiosyncrasy and the symptoms, however diverse the agent, have a great deal

of similarity. Coca has suggested that the term allergy, introduced by von Pirquet, be limited to describe these individual peculiarities.

Because of the ease with which experimental animals may be rendered sensitive or anaphylactic, there has developed a general fear of a fatal outcome following injections of antitoxins and antisera made some weeks or years after a previous injection. There is, however, direct evidence that man is much less liable to be similarly sensitized. In this connection it should be noted that attempts to render monkeys anaphylactic have failed. Longcope believes that the high degree of susceptibility in

some people with spontaneous sensitiveness, the multiplicity or lack of specificity of sensitivity and the distinct tendency to occur in families differentiates these individuals from the artificially sensitized. Man may be sensitized in a way as manifested by the accelerated or immediate reactions of serum sickness, the production of chills and fever by intravenous injections, or by the development of an increased skin sensitivity after serum administration.

Collapse or death has occasionally followed the second injection of antitoxin or antiserum, and seemingly is more likely to occur after intravenous or intraspinal injection where an interval of five days or more has elapsed after the first injection. These occurrences suggest that some individuals may actually be rendered anaphylactic. On the other hand, different lots of antitoxin and antiserum behave distinctly differently, and individuals of known sensitivity do not necessarily always react similarly to the substance to which they are sensitive. The danger of second injections to an individual is probably only slightly greater than that of first injections.

SERUM REACTIONS

The untoward symptoms elicited in man by the introduction of serums with or without antitoxins may be divided into those following the initial injection and those following the second or later injections. These reactions have nothing to do with the antibody content of the injected serum.

Following the first injection three types of reactions may be noted: (a) most frequently, a symptom-complex called "serum sickness"; (b) very rarely, collapse, with or without fatal outcome; (c) equally rarely, local necrosis. Each of these forms of response may follow the second or later injection.

Collapse or Death—This rare accident

has been noted usually after the first injection. The symptoms develop quickly after the administration of the serum. In about 1 to 20,000 persons receiving primary injections of serum alarming symptoms develop; in about 1 to 50,000, death results. The symptoms are those of extreme dyspnea and collapse. The dose which will give alarming symptoms or even result fatally may be very small. Kerley reports a case of known hypersensitiveness where the dose was gradually increased until 4 minims were given; this resulted in alarming shock. It is probable that the greater frequency of deaths after first injections was because the number of first injections was so much larger. The individuals showing this type of reaction are commonly those subject to "hay fever or asthma" developing attacks especially in the neighborhood of horses. Children having a status lymphaticus are prone to develop collapse or die. Every precaution should be taken in giving antitoxins or antisera to such cases or to those subject to asthma.

Chills—A chill more or less severe is observed in about 10 per cent of the cases after the intravenous injection of refined antiserum and about 20 to 60 per cent of the cases after unrefined antiserum, even when injections are given very slowly and the material warmed to the body temperature. In the Willard Parker Hospital the frequent administration of antitoxin by the intravenous method has revealed that this probably depends on some special form of the protein or lipid. With the best product of refined antitoxin globulins less than 1 per cent of intravenous injections produce a chill. There is considerable difference in this respect between different preparations of both refined and unrefined serum.

It should be emphasized that the development of sudden collapse is the condition to fear and prevent. Serum

sickness is not fatal in itself, however alarming in appearance and uncomfortable the condition may be; even where two or even three successive waves of rash and edema ensue. This condition cannot be prevented except by improvements in concentration methods, which will both modify and lower the content of protein substances in antitoxin and other antibody preparations. The giving of divided doses does not materially influence the subsequent development of serum sickness as roughly the total quantity given is the determining factor in individuals of equal sensitiveness and with the same preparation of antitoxin.

Serum Sickness—The incidence of this type of reaction varies widely in different series of cases, being from 10 to 60 per cent or more according to the preparation of serum used. The size of dose will influence to some degree the percentage incidence. Because of the lower protein content and also because of the heating, the concentrated globulin preparations of antitoxin cause a relatively low incidence. Following the first injection of serum or antitoxin there is an incubation period varying from 3 hours to 24 days. More commonly the period ranges from 3 to 12 days. The symptoms are primarily a skin eruption, edema, slight albuminuria, variable both in incidence and in degree, enlargement of the lymph nodes with pain and tenderness and pain in the joints. The eruption is very variable in character. A local eruption usually appears earlier than the general eruption. On the second or later injections the period of incubation may be absent or shortened, "immediate or accelerated reaction," although this does not always occur. This accelerated reaction is not more serious than the ordinary serum sickness. Some samples of unrefined serum uniformly cause skin eruptions (scarlatinaform) earlier than others. The longer incubation periods are more frequently followed by urti-

carial rashes. It would seem from this that there were different reaction-inducing substances in serum or antitoxin.

Severe Local Reactions—In very rare instances the primary injection of antitoxin leads to local necrosis. Although this occurs with extreme infrequency, it should be a warning against injection under the breasts. When repeated injections are given, a second or later subcutaneous injection somewhat more frequently results in a sharp local reaction which may go on to necrosis. This may occur not only with serum but also with rabies vaccine. The resemblance of this form of reaction to the Arthus's phenomenon in sensitized rabbits is marked. The necrosis is not due to bacterial contamination, but the necrotic area may become infected and serious or fatal results ensue.

TESTS USED TO INDICATE THE PROBABILITY OF SERUM REACTIONS

While it is always advisable, in general it is not expedient, to test the sensitivity of every case before the administration of antitoxins or antisera. Careful inquiry should be made as to known allergy, such as hay fever, asthma or food idiosyncrasies. Those giving a definite or suspicious history may then be tested by the intracutaneous injection of about 0.1 c.c. of serum, or antitoxin diluted 1 to 10, or the instillation of a drop of the undiluted serum, or a 1 to 5 dilution in the eye.

It is important that epinephrine be immediately available when doing an ophthalmic test since in rare instances a severe reaction has occurred. The instillation of epinephrine will check the progress of the reaction. Of the two tests, the latter is the more reliable index of the probability of a serious general reaction, but because of crying it is somewhat difficult to use accurately in young children, both because it is partly washed out and because of congestion of the conjunctiva in the other eye.

Untoward results may occur in persons not giving a positive test. The presence of skin sensitiveness, as shown by the prompt development within 20 minutes of a definite wheal at the site of intracutaneous injection which is considerably larger than the original wheal made by the injection, usually indicates that serum sickness with local or general rash will develop, and more quickly than usual. The late area of hyperaemia which develops at the site of the injection is of little if any significance. Children which show this late reaction from an intradermal injection of the serum from one horse often will not react to the serum from another horse. The rare cases with symptoms of shock with or without death are more likely to occur than in those not skin sensitive. The eye test seems to be even a better index of the probability of a serious reaction.

In those where because of history or preliminary test or both there is reason to fear a general reaction, about 0.05 c.c. of serum or antitoxin may be given subcutaneously, and then gradually increased-sized doses, such as 0.1 to 0.2 c.c., given every 15 minutes until a slight reaction indicates that the tolerance of the patient is reached or sufficient serum is given. Should an intraspinal or intravenous injection be required, it becomes a problem of comparative dangers of withholding the serum or risking the reaction. Several preliminary subcutaneous injections may be tried (as above) before attempting intravenous injection, giving then only a very small amount, pausing for some minutes, and then giving the remainder very, very slowly. Dilution with saline solution wherever possible is an aid in this regard.

Even with all these precautions a severe reaction or even a fatal result may occur. Thus, a young woman, who had received 80 c.c. of antistreptococcic serum intramuscularly, required at the

end of 3 weeks an intravenous injection. She was given at short intervals 0.5, 1, 2 and 4 c.c. of serum subcutaneously. No appreciable local or general reaction occurred. An intravenous injection was then given. When the amount reached 10 c.c., while it was being administered very slowly, she complained of premonitory symptoms of beginning shock. The injection was immediately suspended, but the symptoms increased and death soon resulted. The first injection of serum, although it produced no immediate effect, did cause serum sickness on the 8th day. Such cases are fortunately rare.

DESENSITIZATION TO SERUM

Instances are noted with some frequency where first injections have caused reactions and following injections given several hours or even a day later have produced little or none. This would seem to indicate a desensitization. Different batches of bactericidal or antitoxic serum will vary widely in their rash and temperature producing qualities, and this may have been a factor in the development or non-development of symptoms. The administration of small doses of serum, prior to a first large injection or prior to subsequent injections of those known to be sensitive, has not the regularity of desensitization noted in experimental animals. Divided doses may fail to give a reaction or repeated small doses may apparently induce a tolerance, but this is no proof that we are inducing the mechanism of desensitization so uniformly producible in experimental animals. In persons suffering from lobar pneumonia where frequent injections of antiserum are given intravenously the first injection of serum frequently produces a chill. Subsequent injections of the same dose rarely produce one, but if the dose is markedly increased a second chill frequently follows. Even the same amount

of a different preparation is more apt to produce a chill.

METHODS OF ELIMINATING THE REACTING SUBSTANCES FROM ANTISERUMS

Concentration methods (globulin separation) have had effect in reducing the incidence of rashes. Heating the antisera to 56° C. before concentration is of distinct value; likewise the preliminary saturation with sodium chloride and the use of the clear filtrate for the subsequent steps in the ammonium sulphate method of purification. Aging of antisera or of globulin preparations is of distinct value. Crystal clear products are less likely to cause chills and the aging before filtration is more likely to yield a product which will remain clear. Starving of horses prior to bleeding does not seem to influence the content of reacting substances. Keyes and Carey advise the addition of calcium chloride and cephalin to remove the residual fibrin-forming substances still remaining after clotting. They believe that chills may be prevented in this way. In a little preliminary work we have not been able to remove the chill-producing substance by utilizing what we believed to be their method.

TREATMENT OF DEVELOPED SHOCK

Hypodermic injection of epinephrine or atropine will usually relieve the less severe attacks. In extreme collapse artificial respiration may be tried.

EFFECT OF THE SERUM IN TOXIN-ANTITOXIN IN SENSITIZING HUMAN BEINGS TO LATER INJECTIONS OF SERUM

Let us first approach this subject from the experimental side. It has long been known that minute quantities of serum will sensitize guinea pigs so that they will show some reaction after a delay of several weeks to later doses of serum. It is not usually remembered, however, that these small doses frequently do not sensitize guinea pigs to the extent that

any appreciable reaction follows from large intracardial injections of serum. Recently we have given a number of guinea pigs several times the proportional amount of serum which human beings would get from toxin-antitoxin and none of these guinea pigs have died from 1 c.c. of serum injected intracardially. Several showed no symptoms at all; others had slight spasmodic contractions, scratched their nose and showed evidences of slight anaphylactic shock. They all made good recoveries.

Further it should be remembered as already stated, that the guinea pig is far more susceptible than other animals and so probably far more so than man. If we turn to skin reactions, we find as first pointed out by Hooker that after intracutaneous injections of 0.1 c.c. of a 1 per cent horse serum and 3 injections of the old toxin-antitoxin mixture, that these persons showed a year later a marked increase in the number which reacted to a second intracutaneous serum test.

It should be noted that not only did Hooker use a preliminary injection of serum which contained more serum than the 3^d injections of the present toxin-antitoxin mixture, but he also used the old preparation of toxin-antitoxin which contained thirty times as much serum as the present mixture. Repeating his tests on children that had not received a previous intracutaneous injection, I found that there was only a moderate increase in the percentage of skin reactions among those who had received toxin-antitoxin and that none of these were extensive reactions.

From long experience in using preliminary intracutaneous tests to discover those who might show anaphylactic shock, we have learned that only those skin reactions which are extensive suggest the probability of anaphylactic shock or severe accelerated reactions. Those that show minor skin reactions as well as those that show no skin reactions

may develop anaphylactic shock, but do so less frequently. Then we have the final test as to whether a given number of persons who have received 3 injections of the present toxin-antitoxin mixtures show more accelerated reactions or serious cases of serum sickness or true anaphylactic shock or necrosis than those who have not received these injections.

I have had the opportunity of making a comparison in more than 100 individuals who had received toxin-antitoxin and in more than 100 individuals who have not received toxin-antitoxin. The total number of children was obtained by combining several different tests on different groups. In my experience there was no appreciable difference in the reactions following serum injections in those who had toxin-antitoxin and in those who had not. If isolated cases in which marked reactions occur which happen in those who had toxin-antitoxin previously are reported, it is misleading because similar cases could be reported in those which have not received such injections. It is only by comparing the two lots that accurate information can be obtained.

A striking instance of this was the recently published case of necrosis in a

nurse following a second injection of antitoxin which followed ten days after the first injection. The caption over this report was gangrene following an injection of serum in a case which had previously received toxin-antitoxin. We know that an injection of serum following another given 10 days previously not infrequently is followed by a reaction, while the fact that the first injection of serum gave no reaction definitely rules out the toxin-antitoxin given a year previously as being in any way responsible.

There was recently reported to me the case of a young girl who nearly died after a dose of scarlet fever antitoxin. She had not had toxin-antitoxin or any previous serum injection. If she had had, it would have been considered as the predisposing cause.

From my own observations I am not at all worried by the slight degree of skin sensitization which may be produced by toxin-antitoxin. Fortunately, if anyone is worried we can turn to goat toxin-antitoxin or to toxoid. These preparations when they are properly made and when they have successfully passed tests for immunizing potency are equal in value to toxin-horse-antitoxin. This we are doing in New York and probably this change will in time become general.

VITAL STATISTICS

LOUIS I. DUBLIN, PH.D.

The Appendicitis Record of 1926— The mortality from appendicitis in the registration area of the United States has increased steadily since 1900, when there were 9.7 deaths per 100,000 to 11.4 in 1910, 13.4 in 1920 and 14.9 in 1924. The rate has risen much more slowly in England and Wales from 6.7 in 1915 to only 7.4 in 1925. Since the mortality from normal operations should not exceed 2 per cent, early operations would seem to be of utmost importance in

lessening our mortality from this disease.

The urban death rate in this country has increased from 13.3 in 1910 to 15.6 in 1920, and 17.3 in 1926. In 22 cities of between 50,000 and 375,000 population the average rate was 15.7. Several of these cities reported no deaths, but Little Rock, Ark., had the exceptionally high rate of 61.9. In 116 other cities of more than 20,000 population the average death rate was 17.0 in 1925 and 17.3 in 1926. For disease increase in 65 of these cities

the lowest rate was 0.4 in Indianapolis, Ind., in 1926. The cities with the highest rates were Schenectady, N. Y., 30.1, Denver, Colo., 30.9, Knoxville, Tenn., 31.4, Columbus, O., 32.6, Spokane, Wash., 33.0, Nashville, Tenn., 33.6, Springfield, Ill., 35.5, Petersburg, Va., 35.7, Sacramento, Calif., 36.8, Salem, Mass., 39.6 and Lincoln, Neb., 46.8.—Frederick L. Hoffman. *Spectator*. 120: 11, 29–30. (Jan. 5), 1928.

Vital Statistics of Toronto, Ont., 1927—A review of the vital statistics for the past year shows the general mortality rate for Toronto to be 11.0 per 1,000 of population. This rate is slightly lower than in 1926, and a shade higher than the average annual death rate of the past 5 years, which is 10.7. Some idea of the progress that has been made can be gained when one realizes that the death rate 18 years ago was 15.3. The birth rate for the city, which has been steadily decreasing from the highest rate recorded, 30.9 in 1913, the year immediately preceding the Great War, shows a slight increase over the lowest rate on record, 21.3, a year ago. The rate this year is 21.7, and represents a total of 12,340 live births that were registered.

An infant rate of 158.5 per 1,000 live births (corrected) in 1909 has been lowered by preventive measures, to a rate of 58.8 in 1927, the lowest rate for the city recorded. This is a reduction of almost 63 per cent. The number of infant deaths registered in 1927 was 853, compared with 868 a year ago. The chief cause of death among infants was prematurity, which shows a slight increase over the figure of 1926. An increase is shown this year in gastrointestinal diseases under 1 year, 93 such deaths being registered. In 1913 over 500 deaths occurred from this cause. Decreases are shown in the number of infant deaths from pneumonia, congeni-

tal debility, tuberculosis and acute communicable diseases, compared with 1926.

—The number of deaths from all forms of tuberculosis in the past year was 351; in 1926 there were 329 deaths registered. The mortality rate is 61.6 per 100,000 population, slightly in excess of last year. The reduction made in the tuberculosis death rate has been remarkable, when we compare the rate of 130 in 1910 to the lowest rate on record, 59.0 in 1926, a decrease of almost 55 per cent. The so-called degenerative diseases, organic heart disease, cancer, diseases of the arteries, cerebral hemorrhage (apoplexy), and nephritis (Bright's disease), accounted for approximately 40 per cent of all deaths registered. An increase is shown in all these diseases compared with a year ago, with the exception of nephritis. Fewer deaths were registered this year from pneumonia and influenza. A decided increase has been shown in the number of cases reported to the Quarantine Division of acute communicable diseases, with the exception of whooping cough. Increased mortality, however, is only shown in scarlet fever and diphtheria. Six deaths were due to typhoid fever, compared with 8 a year ago. One death was registered from smallpox, the first since March, 1924. Ten deaths were due to measles, a decrease from a year ago of 2. Twenty deaths from whooping cough, a decrease of 17. Diphtheria accounted for a total of 112 deaths, compared with 89 in 1926.—Dept. of Public Health, Toronto. *Monthly Report*. p. 1–2 (Dec.), 1927.

Vital Statistics in France—The Health Organization of the League of Nations has issued a handbook which deals with the procedure followed in gathering the official vital statistics of the French Republic. The census is taken quinquennially and is planned,

first, to enumerate the legal population for purposes of government and taxation and, second, to ascertain specific data of all persons. Since 1896 the alternate censuses have concentrated on civil condition and occupation, but in 1921 the census included both. The census agents are appointed by the mayors of the communes and are each responsible for a district containing from 100 to 200 persons.

Births of living children must be declared to the registrar within 3 days by the father, doctor or some other appropriate person under penalty of fine or imprisonment. Stillbirths must also be declared and there are special provisions for the recognition of illegitimate children by the parents. Deaths must be declared to the registrar by a relative of the deceased or other appropriate person. Declaration is commonly made within 24 hours, although no time limit is prescribed. The body must in all cases be viewed by an authorized verifier and an "acte de deces" drawn up by the mayor of the commune or his deputy. The acte contains no information as to cause of death, but the registrar in most communes submits to the mayor a special bulletin which among other facts gives the cause of death. But since the medical practitioner in attendance is not required to give a certificate as to cause of death the official records of the verifier vary in reliability. These bulletins are transmitted by the mayor through the prefect of the department to the General Statistical Office where they are published in the *Statistique du Mouvement de la Population*.

There are 18 infectious diseases which are compulsorily notifiable and 9 others which are optional. Notification must be made immediately and in duplicate by the medical practitioner, public health officer or midwife to the prefect of the department and the mayor of the commune. In order to insure professional secrecy the disease is referred to

by number only. A register of notifications is kept by the prefect who sends a monthly summary to the Department of Health of the Ministry of Labor, and a general statement based on the summaries is published annually. A bacteriological laboratory is provided free of charge for medical practitioners in most departments and large towns.

Disinfection, free of charge, to poor persons and on a sliding scale of expense to others, is absolutely required in compulsorily notifiable diseases. Vaccination and revaccination are compulsory. There are 500 dispensaries and 54 sanatoriums with 7,000 beds for tuberculosis, one of the optionally notifiable diseases. For venereal disease, which is not notifiable, there are dispensaries and special facilities for pregnant women, nursing mothers, soldiers, sailors, prisoners and prostitutes.—*Brit. M. J.*, 2:1198-1199. (Dec. 24), 1927.

Vital Statistics of Ghent, Belgium, 1926—The report of the Municipal Bureau of Health of Ghent for the year 1926 gives the population of the city as 162,641. There were 2,356 births during the year as compared with 2,471 in 1925, the rates being 14.41 per 1,000 population in 1926, and 15.08 per 1,000 in 1925. There were 2,078 deaths in 1926 as compared with 2,123 in 1925. Deaths among children under 1 year were 213 in 1926, as compared with 260 in 1925.

The principal causes of death in 1926 were cancer, 226 deaths, and pulmonary tuberculosis, 116. Forty-eight cases of typhoid fever were reported with 4 deaths; 51 cases of scarlet fever with no death; 44 cases of diphtheria with 2 deaths; and there were 6 deaths from whooping cough. One case of puerperal fever and one of cerebrospinal meningitis were reported, but there were no deaths from these diseases. It is said that smallpox has not appeared in Ghent for a number of years. Forty-nine cases of

gonorrhea and 2 of syphilis were discovered and segregated.—*Pub. Health Rep.*, 42:3099 (Dec. 16), 1927.

Vital Statistics of 67 American Cities, 1927—The general death rate for these cities in 1927 was 12.3 as compared with 13.2 in 1926. The three highest death rates occurred in cities having large negro populations. Memphis led with a rate of 19.3; next came New Orleans, 18.7, and Nashville, 17.5. The lowest rates were 9.2 in Somerville, and 9.3 in Yonkers. The highest rates in 1926 were found in the same cities as in 1927, Memphis 20.0, Nashville 19.7 and New Orleans 18.9. The lowest rates were in Seattle, 9.7 and in Yonkers and Canton each with 10.4.

In 1927 the infant mortality rate was 62 and in 1926 it was 72 per 1,000 live births. The highest rates in 1927 were 87 in Lowell and 85 in New Orleans; in 1926 the highest rates were 107 in Richmond and 102 in New Bedford. The lowest rates in 1927 were 36 in St. Paul and 37 in Seattle, in 1926 they were 39 for Portland, Ore., and 46 in San Diego. *U. S. Weekly Health Index*. Summary for 75 cities, 1927.

Vital Statistics of Syracuse, N. Y., 1927—The general death rate in Syracuse for 1927 was 12.3 as compared with 13.3 for 1926. The infant mortality rate was 57.3 as against 69.2 in 1926. Of the 6 principal causes of death, only cancer and nephritis showed slight increases. The tuberculosis mortality rate of 59.0 was the lowest rate of any large cities in the United States. There were 584 deaths from heart disease in 1927, from cancer, 242, from pneumonia 206, from nephritis 195 and 169 from cerebral hemorrhage.

There were 14 deaths from measles, 3 each from diphtheria, scarlet fever and typhoid fever. These deaths from typhoid fever were traced to a typhoid carrier in the city. There were 168

deaths from violence in 1927 as against 176 in 1926. The total number of deaths from tuberculosis and all the acute infectious diseases, with the exception of pneumonia, was much less than those from violence.—*Syracuse Better Health* (Monthly) 2:2-3 (Jan.), 1928.

Statistics of Attendants at Birth in Pennsylvania—Hospital births comprised only 19 per cent of all births in Pennsylvania during 1926 but in Philadelphia 41 per cent took place in hospitals. Twenty per cent of native born mothers in the state went to hospitals for confinements, 36 per cent of colored mothers and 14 per cent of foreign mothers had hospital care. The high percentage of hospital confinements among colored women is partly explained by the fact that most colored people in Pennsylvania live in cities with easily accessible hospital facilities.

Seventy-four per cent of births occurred in the home of the mothers and were presumably attended by physicians while 7 per cent were attended by midwives. More than 60 per cent of the mothers attended by midwives were foreign born. Of all births among foreign born mothers 22 per cent were midwife births but only 4 per cent of native born white and colored mothers employed midwives. Midwife births were highest among those of Polish birth, and next among the Austro-Hungarians. The Irish, Italians and Germans employ midwives for from 10 to 20 per cent of the births. Russian and British mothers are rarely attended by midwives.

There were 4,681 illegitimate children born in Pennsylvania in 1926, amounting to 2.2 per cent of all births. Illegitimate births made up 9.5 per cent of all colored births, 2.7 per cent of the children of native born mothers and 0.6 per cent of children of foreign born mothers.—*The Hurry Call, Pennsylvania's Health*. 6:29-30 (Jan.-Feb.), 1928.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C.E.

SEWAGE SLUDGE*

C. B. HOOVER, FELLOW A. P. H. A.

Columbus, O.

AFTER more than one-third of a century of practice of the art of sewage treatment in the United States, the disposal of sludge holds the center of the stage as a most troublesome and exasperating problem.

Sewage solids, deposited in a settling tank, and not properly digested before being withdrawn, are very apt to create a decided odor nuisance. If digestion has been satisfactory, but the sludge drawn from the tank has a high moisture content, then the problem of dewatering is presented inasmuch as this step must be taken ordinarily before final disposal can be made.

There have been three general means employed for the final disposal of sewage sludge; namely, (1) discharging it in deep water of a lake, sea or ocean where it will not create a physical nuisance or be otherwise objectionable; (2) spreading it upon farm land with the idea of utilizing any fertilizing value it may have; and (3) using it for making fills.

In every community where sewage treatment is practiced, there are citizens and public officials, who, because of their interest in public affairs, want to know why sewage sludge cannot be used as a fertilizer and possibly become a source of revenue.

No effort will be made in this paper

to give a definite answer to this question. However, a better perspective of the problem and its limitations may result from a study of the results of 16 years of experience by the City of Columbus, O., in the recovery of salable products from another municipal waste, namely, garbage.

During the period from 1911 to 1926, both years included, 361,773 tons of green garbage were reduced, resulting in a recovery of 8.8 per cent of the original green garbage tonnage as tankage or fertilizer, and 2.5 per cent as grease. The total revenue from the sale of by-products was \$1,367,679 and the total cost of operation (\$1,183,040), interest on bonds (\$198,450) and free water (\$126,076), was \$1,507,566.

The total revenue per capita per year was 36.8 cents, and the average cost of operation, interest and free water per capita per year was 40.6 cents, making the net cost per capita per year, not including depreciation, 3.8 cents.

The costs referred to above include the cost of transportation of the green garbage from a central loading station to the reduction works but do not include the collection cost.

If a proper depreciation charge were added, the average net cost per capita per year would be approximately 10 cents, and although this plant has not been a net producer of revenue, its operation has provided a very cheap method of garbage disposal.

A further study of this recovery

* Presented to the Public Health Engineering Section of the American Public Health Association, at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927. (See Report of Committee on Disposal of Sewage and Industrial Wastes, *A. J. P. H.*, Feb., 1928, p. 199.)

process shows that of the total revenue for the 16-year period, 73.0 per cent was derived from the sale of grease, 24.5 per cent from the sale of tankage or fertilizer, and 2.5 per cent from other miscellaneous sales, such as hides, etc., and a still further analysis of the salable products shows that the contributing elements were approximately as follows:

	Per cent
Grease	73.0
Nitrogen	20.0
Phosphorus and potassium	4.5
Other products	2.5

The above data show that grease and nitrogen recovery accounted for 93.0 per cent of the revenue derived from the sale of the by-products of garbage reduction.

The average pounds of green garbage per capita per year for the 16-year period was 195, and of this amount 80 per cent is moisture and ash and 20 per cent combustible matter. Inasmuch as the combustible matter furnishes the grease and nitrogen which account for 93 per cent of the salable by-products, consequently the valuable recovery products are produced from 20 per cent of 195 lbs. or 39 lbs. of dry material per capita per year.

For purposes of comparison it will be assumed that average municipal sewage has 200 p.p.m. of suspended solids; that the entire amount is removed by the treatment process and recovered as sludge; that the sewage flow is 100 gals. per capita per day; and that 40 per cent of the total suspended solids are fixed, and 60 per cent volatile.

Under the above assumptions the combustible matter in sewage per capita per year would be 200 p.p.m. x 100 gals. per capita per day x 365 days x $8\frac{1}{3}$ lbs. per gal. x 0.60 divided by 1,000,000, or $36\frac{1}{2}$ lbs.; or in other words, on the basis of the assumed conditions, taken as average for municipal sewage, there is less dry combustible matter in sewage per capita per year than there is in garbage.

The above estimate of $36\frac{1}{2}$ lbs. contemplates a complete recovery of the suspended solids, whereas very material losses will occur from at least three sources; namely, a portion disappearing as a result of digestive processes, another portion being unrecoverable because of its finely comminuted condition, and a third portion passing out with the final effluent of the works.

There is also a marked difference in the quality of the ether soluble material in sewage sludge and garbage. The unsaponifiable material in garbage grease is less than 3 per cent, and the grease from sewage sludge has been reported by one investigator to have an unsaponifiable content of from 7 to 14 per cent, and others have placed it as high as 20 per cent.

The average amount of grease recovered from garbage at Columbus for a period of 16 years is 4.8 lbs. per capita per year, and the average selling price is 5.65 cents per lb. The average amount of grease in sewage is somewhat speculative inasmuch as fat determinations are not a part of the analytical routine in sewage works laboratories. During the experimental investigations in Columbus in 1904 and 1905, fat determinations were a part of the routine analysis and the average value secured at that time indicated a fat content of about $7\frac{1}{2}$ lbs per capita per year; however, the hardness of the city water at that time was about three times the present hardness, also the use of automobiles had barely started at that time.

About ten years ago, $15\frac{1}{2}$ tons of air dried sewage sludge were put through the drying process at the garbage reductions works with the results shown on the next page.

The composition of the dryer sludge was, ammonia 1.86 per cent, potash 0.11 per cent, tri-calcium phosphate 2.72 per cent; and the selling price of this dryer sludge at present-day prices would be \$3.88 per ton.

Total weight of air dried sludge	15.5 tons
Moisture in air dried sludge	24.8 per cent
Total weight of dryer sludge	6.5 tons
Moisture in dryer sludge	3.4 per cent
Total loss in drying treatment	0.0 tons
Moisture loss in drying treatment ...	3.6 tons
Loss of other constituents	5.4 tons
Per cent dry recovered sludge was of original air dried sludge	42.0.

It is probable that the method employed to dry this sludge caused a material loss of nitrogen and was not the best way of doing it.

The per ton selling price of garbage tankage for the 16-year period has been as follows: average \$10.45, maximum \$22.65, minimum \$6.96. The prices

received in recent years for garbage tankage are as follows: 1924, \$9.35; 1925, \$8.86, and 1926, \$8.20.

Columbus has a present population of approximately 295,000, with a wide diversity of industries, none of which produces wastes unusual in quality or particularly large in quantity. The sewage of the city is probably of average domestic industrial composition.

In conclusion it would seem that, under the conditions just reviewed, an attempt to recover valuable products from sewage sludge is not a promising undertaking and that the proper criterion is in finding the cheapest and most satisfactory means for its final disposal.

Study of the Waste Water of Paper Mills—The author reports a number of studies and experiments made by himself on waste waters from paper mills in an effort to determine the significance of this particular industrial waste as affecting the health of the population in certain areas, its effect on fish life in streams into which it is discharged, and its possible application to soil as a fertilizer-carrying irrigation water.

Three kinds of waste were experimented with which the author designates as I, II, and III as follows: (I) Straw and lime, or paper board refuse; (II) manila hemp, *Broussonetia Kashinoki*, Sieb and other materials used in the making of Japanese papers; (III) wastes in which above two are combined.

Interesting charts and tabulations of the detail technic are given covering each type of experimental study and the author's conclusions are given below:

Effects of Waste Water on

1. **Pathogens**—This experiment was limited to a study of the effect of paper mill waste on *B. typhosus*, cholera vibrio and dysentery bacilli. No apparent germicidal power was noted in fluids I and III, but fluid II destroyed the cholera vibrio in 8 hours, typhoid bacilli in 4 to

8 hours and dysentery bacilli in 2 to 4 hours when used in its original form (without dilution). Diluted to one-half strength cholera spirilla were destroyed in 8 to 18 hours, typhoid bacilli in 8 hours and dysentery bacilli in 4 to 8 hours by fluid II.

2. **Fishes**—This series of experiments indicates that "fish die in the waste water when the latter decomposes to degeneration"; it does not destroy them in a short time; and "that the fish which lived long in such waste water acquired some peculiar odor and was unfit for eating."

3. **Animals**—Rabbits were used as the experimental animals and it is interesting to note that the animals fed with fluid I and fluid II showed a gain in weight of from 31 to 78 g. more than control animals which were caused to drink "plain water."

4. **Plants**—The author assumes that paper mill wastes should be an excellent medium for the fertilization of growing crops when used for irrigating land since it contains the essential elements of plant food and is "almost free from injurious elements."

Unfortunately, his experimental rice field was attacked and destroyed by rats

during the course of his experiment and the continuation of this study is left to the Prefectural Experimental Firm under the guidance of which the Seihl Paper Mill is now conducting similar experiments.

Experiments on Decolorization of Waste Water—A considerable number of experiments were conducted with different chemical agents and varying dilutions of the waste in order to determine the most effective method of accomplishing decolorization. Local inhabitants appear to object more strenuously to the filthy appearance of water polluted by such waste than to its actual chemical composition. The author concludes that "decolorization by means of sodium bisulphite and dilute sulfuric acid cannot be thoroughly effective."

Experimental Dilution of Waste Water—Dilutions of paper mill waste of varying strengths from 1:100 to 1:600 were made of fluids I, II and III and the dilutions examined as to appearance, odor, reaction, and analyzed for the presence of sulfuric and nitric acids, ammonia, chlorine, lime and organic matter. These experiments are carefully tabulated.

The conclusion is that "said waste water becomes drinkable if diluted to 600 times with distilled water, and 700 times with water from the river Matsubara."

Course Taken in Decomposition of Waste Water—This series of experiments was made to determine the effects of dilution alone on the putrescibility of waste waters. It was observed that while the original fluid decomposed and changed color by the third day, 1:5 dilution on the 10th day and 1:10 on the 15th day, "It was also seen that in the progress of decomposition much depended on temperature and sunshine." A dilution of 1:20 never decomposes or changes, even in the month of August.

The Effect on Sanitation of the Districts along the River to Which the Waste Waters Flow In—(1) Mosquito

breeding is increased and breeding season prolonged. (2) Fishing, swimming, and such recreations are interfered with or made impossible. River is changed from beautiful, clear stream to one of filthy, foul, malodorous character with its beauty spoiled. Fish are entirely destroyed. (3) A variety of gases are generated in the water. Air along the river bank contains 1 part per 3,000,000 of hydrogen sulfide. The foul odor varies according to the day, hour and place.

It is the author's opinion that some means should be devised for using paper mill waste for fertilizer unless it can have a dilution in the stream receiving it of at least 1 to 500.—Natsuhiko Watanabe. *J. Pub. Health Assn. of Japan*, 3:1 (July), 1927. Abstr. C. H. Kibbey.

Direct Microscopic Examination of Milk—The article describes detailed experiments by the authors to determine value of direct bacterial count of milk as evidence of its sanitary quality.

Ten c.c. samples were centrifuged, a smear on slides made of sediment and this defatted, fixed, clarified, stained and examined under X900 magnification. Comparisons of direct count results, with field examination of cows suffering from mastitis, showed close relation between the two.

Dilution tests of certified milk contaminated with milk from infected cows indicated that it could be detected in high dilution.

Examination of dairies and market milk was begun and the direct counts found to parallel the conditions of the cows and sanitary conditions of the dairy. This visible method roused the interest of the dairymen, secured their coöperation and resulted in improved relations between inspectors and dairymen.—LeRoy Forman and I. H. Shaw. *Health News*, N. J. State Dept. of Health, 12:143 (May), 1927. Abstr. J. R. Hoffert.

The Volga, Oka and Moskowa Rivers as Sources of Supply of Potable Water for the City of Moscow—The water supply of the city of Moscow comes from two places: the underground stream of Mytizchy provides 25,000 cu.m. per day, and 170,000 cu.m. per day are taken from the River Moskowa.

The population of Moscow being, according to the last census, over 2 million, the supply is only sufficient for the metropolitan area. It is estimated that, in 1950, 630,000 cu.m. will be required, and in 1933 that 300,000 cu.m. will be required to supply the environs of Moscow as well. The Moskowa cannot supply more than 260,000 cu.m. per day; so a commission was appointed to find other sources of supply. Two other rivers, the Volga and the Oka, were investigated. As the distance from these rivers was 100 km. they appeared impracticable for this purpose, a more practical solution seeming to be the impounding of the Moskowa to provide a constant supply and to lessen the risk of floods as well. Nevertheless, tests of the waters of the Volga and of the Oka were made, with recommendations as to their use. It was considered that because of the origin of the waters of the Moskowa, it would cause great trouble due to algal growth, and the necessary measures to provide a potable water if reservoirs were formed would be to withdraw the water at a certain depth, to withdraw a constant amount, to clean out the reservoirs with the surplus of the spring floods, to drain the marshes and low places before inundation, and to provide a sanitary zone around the edge of the impounded area. —S. N. Stroganoff and N. G. Zakharoff.

Résumé of *Report of Communal Service of Moscow, 1927* (Russian). 186 pp. Abstr. W. H. W. Komp.

Many Algae Growths that Annoy the Water Works Man—Fresh water algae are classified into three groups: (1) The red algae group which contains 17 varieties; (2) the green algae division which has 356 species; (3) blue green algae which numbers 232 plants. The odor produced by the various algae may be sweet, grassy, geranium-like, fishy or obnoxious. Algae must have CO₂, nitrogen and sunlight for their growth and development. The nitrogen may be obtained from the nitrates in the water. Copper sulfate is now widely used for the destruction of algae. Chlorine is also used in some places. Copper is probably not a true poison. Doses as high as 15 grains have been prescribed in medicine.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH.D.

Spray Painting in Pennsylvania—
This bulletin of 201 pages including tables, and a short bibliography covers the extensive investigation made by Henry Field Smyth, M.D., and his co-workers under the direction of Richard H. Lansburgh, Secretary of Labor and Industry, Pennsylvania. While the report is dated November 3, 1926, it came off the press late in 1927. Following a 3-page Foreword by Secretary Lansburgh which discusses the organization of the investigation, there follows a detailed description of the 233 plants visited; a report to the advisory committee divided into: Part I, Field Survey, comprising the first 128 pages; Part II, Chemical Engineering Work, to page 192. A special study upon the effect of butyl and amyl acetate vapor on guinea pigs, which arrived at the conclusion that the latter appeared to have no effect upon the pigs while the former is somewhat toxic, comprises a 4-page report.

Careful studies were made of air velocity, benzol, lead content of air, and suspended particles in the air. Urine analyses, blood findings, and a detailed discussion of symptoms of poisoning, are given. Carefully controlled laboratory experiments upon different concentrations of benzol in the air, and upon the accuracy of different methods of determination include the most reliable data which have yet appeared upon this subject. The summary and conclusions follow:

1. The purpose of the study was to determine whether there is a health hazard involved in the coating of surfaces with paint, varnish, lacquer, shellac, enamel, and similar materials by the spray method; and if such hazard is present, in what manner it is manifested and to what extent.

2. In the field survey 233 establishments were visited; 383 physical examinations were made; 168 air velocity measurements were taken; and air was sampled and determinations made for the presence of benzol (91 samples), total solvents (10 samples), lead (22 samples), and dust particles (26 samples).

3. No cases of marked ill health which could be attributed to the work of the individual examined, were found, although some histories to this effect were obtained.

Mild symptoms of benzol absorption were found in persons spraying lacquer, substitute shellac, and stain. Blood examinations showed specific changes, which, while not so far advanced as to produce definite symptoms, were of such character as to indicate the absorption of benzol in its early stages.

Evidences of slight lead absorption were found in some sprayers of lead, but no cases of acute lead poisoning were met.

In the sprayers of vitreous enamel and other siliceous materials, X-ray photographs of the chest showed, in a few instances, definite fibrosis, and in others, lesions suggestive of beginning fibrosis; these two groups comprising not quite one-third of the total number examined.

4. Exhaust ventilation was studied through laboratory determinations. In these, a commercial booth was used for the spraying of objects of dissimilar sizes and shapes with material of different but known benzol content under varying conditions.

5. The health hazards encountered in spray coating processes may be overcome by the use of materials of nontoxic and nonirritating character, by the use of materials in which these elements are reduced to a minimum, and by requiring that when the spraying process is used certain definite precautions must be observed. With this in mind the Department of Labor and Industry has formulated tentative regulations covering this subject which will be discussed at public hearings and which will then form the basis of the regulations adopted and enforced by the department.

6. As the composition of lacquers has not yet been standardized and as almost all lacquer makers are continually changing their formulae and attempting to use entirely new solvents, the effect of which upon the health is or may be unknown, we feel that the indicated pre-

cautions will be advisable even though benzol itself may be entirely eliminated.

—Pennsylvania Dept. of Labor and Industry, *Special Bulletin No. 16*, November 6, 1926.

Final Report of the Committee on Spray Coating—This bulletin of 53 pages includes numerous illustrations, tables, and extensive infolds bearing tables showing, for instance, the findings for lacquer sprayers, undercoat and paint sprayers, vitreous enamel sprayers on sheet metal, and on castings. The National Safety Council created a special committee with A. L. Watson as chairman, which appointed a spray coating committee of 23 members, with Professor C.-E. A. Winslow as chairman, the efforts dating back to October, 1925. On June 4, 1926, Henry Field Smyth, M.D., and his associates, who had just completed the Pennsylvania study (above referred to) was invited to undertake this investigation. The work was done in Detroit and Toledo, except that enameling plants in Mansfield and Cleveland were also visited and studied. The field work was completed in September, 1926. Altogether, 29 different plants (or groups of workers) were studied. Eighty-six air tests were made for benzol, 27 for lead, and 33 for silica. A total of 354 physical examinations were made, including 349 blood tests.

The present report considers the historical development of the problem, spray paint constituents for both interior and exterior work, benzol poisoning, lead poisoning, and silicosis as a spray coating hazard, and the protection of workers by various means, such as the use of masks or respirators and the efficiency of same, medical supervision, the prevention of fire hazard, and the elimination of injurious materials. Approximately 30 pages are given to appendices which discuss in detail the methods used and the clinical findings for benzol, lead, and silica exposed workers (by Henry Field

Smyth, M.D.); and the efficiency of respirators which might be used with the dangerous substances mentioned (by S. H. Katz, E. G. Meiter and F. H. Gibson of the U. S. Bureau of Mines Experiment Station).

The final conclusions read as follows:

We would then urge as our most important and fundamental recommendation that manufacturers of paints, lacquers, shellacs, varnishes and vitreous enamels to be used in spray coating should so far as possible eliminate benzol, lead and free silica from their products and where this has been done should clearly label such products as containing less than a certain maximum amount of lead or benzol or free silica as the case may be; and that employers using the spray gun for indoor and booth work should so far as possible insist on obtaining and using only materials so labeled.

A minority report signed by two members of the committee raises 8 points of dissension and is included upon the last page of the bulletin. These chiefly concern details of the conclusions which the two signers thought were not well founded.—National Safety Council, Chemical Section, Chicago, 1927.

Annual Report of the Ontario Division of Industrial Hygiene—Sickness and accidents are responsible for at least 75 per cent of all absence from work. The employer pays directly for accidents in Ontario, 7 or 8 million dollars per year. He also pays for sickness which costs several times as much. Wage earners in Ontario lose about 30 million dollars a year in wages on account of ill health in addition to all the anxiety and suffering. While occupational diseases are included in this estimate, it is largely made up of the same group of illnesses which affect the general population, e.g., colds, bronchitis, pneumonia, rheumatism and sore throat. About half of the lost time caused by these illnesses can be prevented. This may be done by (1) knowing the material (workers) with which the work is done, (2) periodic supervision of those engaged, and (3) establishing

facilities for promptly dealing with the first indications of a breakdown in an employe. The physician must be brought to the patient.

The division has prepared a booklet, *Occupational Diseases: A Ready Reference Manual*, for distribution. Physicians are using more extensively the division laboratory. Among the chief occupational diseases discussed are those due to lead, which is of chief concern in the storage battery plants, but the general conditions are very favorable in Ontario in this industry since the large manufacturers have made provisions for periodic physical examinations. Lead mining was found to have a few mild cases of lead poisoning. Lead sulphide is the form of ore. Ethyl gasoline is another possible source of lead poisoning which is being watched.

During 1926, 1,040 miners in northern Ontario quarries were given a physical and X-ray examination. In April, 1926, the Workmen's Compensation Act of Ontario was amended to include silicosis, and since that date 97 cases have been compensated. To cope with this condition steps are being taken to examine all men employed under ground at sufficiently frequent intervals to hold the disease in check. So far, the division has received reports of 50 cases and 3 deaths from caisson disease which have been compensated. A study has been made of nickel rash in electro-plating rooms and a quite satisfactory disinfectant has been found, to be used with cutting compounds and cutting oils. In one large iron and steel plant no cases occurred for a period of 6 months after the use of the disinfectant was started. Ventilation studies have been made in paper plants and in cotton and wool plants, also in two schools in Hamilton. As a result of work which has been done in the reduction of infection following injuries, a plant previously notorious for the number of infected injuries, employing 800 men for the year 1926, among

1472 cases of injury, had only 7 infected cases, which caused a loss of 68 days and a cost of \$285.

Cyanogen chloride is being used for fumigation of bunk houses as a safer disinfectant than hydrocyanic acid, since the former has a tear-gas effect which serves as a warning.—J. G. Cunningham, *Annual Report*, Ontario Department of Health, 1926, pp. 18-23.

Resolution On Preventive Medicine Is Endorsed—Dr. L. F. Stewart (Consulting Surgeon, Pennsylvania Casualty Co., Clearfield, Pa.) reported:

Your committee appointed at the morning session of the Health Service Division presents the following for action:

1. That this body believes that it is proper and right that industry, through its medical department, should take all steps possible along the lines of preventive medicine so far as the employe and his family are concerned. Sanitation, examination of the employe, and the general prevention of disease along the lines of health education and the general employe's welfare are not only proper but essential.
2. That it is the opinion of that conference that all accident cases occurring to the employe of a company in the course of his employment should receive proper surgical attention without limit under company supervision in an effort to promptly restore him to his usefulness.
3. That it is the consensus of opinion of this conference that so far as medical attention to the employee is concerned the policy of many corporations wherein they give diagnostic aid in co-operation with the families be endorsed, and that the company lend every assistance to the family physician in returning this employee again to his work.
4. That it is the consensus of opinion

of this conference, except in isolated points, wherein it is impossible for the employee to obtain proper medical and surgical attention, that it is not advisable for the family to receive medical attention either at a stipulated stipend or at the expense of the corporation.—(Signed) S. R. Benedict, W. A. Sawyer, F. E. Clough, L. F. Stewart. *Trans. Natl. Safety Council*, General Sessions, Sixteenth Annual Safety Congress, 1927. p. 249.

Deaths from Lead Poisoning—Lead continues to occupy a position of supreme importance as an industrial poison, and for this reason the present bulletin prepared by Dr. Hoffman in his usual thorough manner is of much interest and value. In this volume Dr. Hoffman has analyzed the available statistics of chronic lead poisoning in the United States, Canada, Great Britain and certain other foreign countries. In addition to this there is presented an analysis of deaths from chronic lead poisoning in the U. S. Registration Area from 1914 to 1924. These death certificates are further classified by occupation and age, and in certain cases statistics concerning contributory causes of death are presented and analyzed. Lastly, in Part 3 of the bulletin, are presented the statistics for chronic lead poisoning from 4 state accident boards, namely Massachusetts, Pennsylvania, California and New York.

It is obviously quite impossible in a brief abstract to present Dr. Hoffman's findings in any detail. The death statistics of the U. S. Registration Area as well as those of the Metropolitan Life Insurance Company show that the death rate has been declining since the year

1912, and now, according to these data, has reached the rate of 1.6 per million persons exposed. The rates for white males and for colored males appear to be very nearly alike.

The largest number of deaths took place in the occupational group of painters, and but 62 occurred in the group of lead workers in smelting plants, etc.

The worker in the field of industrial hygiene cannot fail to be interested in this report and to those interested in the problem of lead poisoning it is of great value.—Frederick L. Hoffman, *Bull. No. 426* U. S. Bureau of Labor Statistics, Washington, Feb., 1927. L. G.

Occupational Diseases in the U. S. Navy—Carbon monoxide, illuminating gas, etc.—There were 6 admissions and 5 deaths. In 1 case, poisoning was reported as complicating another disease or condition. Illuminating gas escaping from a heater was reported as responsible for 2 deaths, gas from a range for 2, and gas from a jet for 1. One patient poisoned by carbon monoxide recovered.

Poisoning by volatile substances, bilge gas, etc.—Admissions were reported as follows: bilge gas, 3; copper and zinc fumes, 1; marihuana plant, 1; trinitrotoluene (TNT) fumes, 2; and turpentine fumes, 1.

Poisoning by lead—There were 37 admissions. Fifteen cases of acute poisoning by lead paint, manner not specified, were reported, and 5 cases were reported in which acute poisoning was attributed to particles or dust from paint. Nine cases of chronic lead poisoning caused by paint were reported—*Annual Report of the Surgeon General, U. S. Navy, 1927*, p. 245.

water, both immediately after inoculation and after the inoculated samples had stood for one half hour. *Bact. typhosum* was used as the test organism. Water sterilized with the 110 volt lamp with an energy consumption of about 300 watts showed no evidence of any residual germicidal activity. When 400 to 600 watts were being consumed, we were able to recover from the irradiated specimens about 40 per cent less bacteria than from the controls. With the 220 volt lamp, consuming about 700 watts, we recovered 28.5 per cent less bacteria from the sterilized than from the untreated specimens. With energy consumption between 800 and 1600 watts this percentage was 42. It is difficult to explain these results on any other basis than that of a residual germicidal action in the irradiated water. The counts were consistently lower with the treated water, although the differences were not constant in different experiments. We were never able to kill all the bacteria added to irradiated water even when the number of organisms used was as low as 100 per c.c. No indication of a residual germicidal action was obtained on samples which were allowed to stand for one hour after sterilization and before inoculation.

When *Staph. aureus* was used in place of *Bact. typhosum* we were unable to find any evidence of residual germicidal action. A few experiments using a strain of the Friedländer bacillus gave results similar to those obtained with the typhoid bacillus.

These results indicate that water after exposure to ultra-violet light of sufficient intensity may show some germicidal activity. We were anxious, however, to make a further study to determine more definitely the factors concerned. While our experimental work is incomplete, we should like to present the results obtained to date.*

Various solutions were exposed in 100 c.c. amounts in 8 inch Petri dishes, to a 220 volt mercury vapor lamp. The actual voltage across the lamp was 150 and the amperage was 3. During exposure the solutions were kept cool by a coil through which cold water was circulating and which served to support the Petri dish. The temperature in the exposed solution never rose above 40°C. The time of exposure was varied but the results obtained after long irradiation (i.e. 30 minutes) were no different from those after 2 or 5 minutes exposure. Immediately after irradiation the solutions and unexposed controls were inoculated with a washed 24 hour broth culture of *Bact. typhosum*, (Rawlings strain). After shaking to obtain as even as possible a distribution of bacteria, a 1 c.c. portion was removed and used to seed a nutrient agar plate. Fifteen minutes later a second portion was removed. Colony counts on the agar plates were made after 24 hours' incubation at 37°C. All

* October, 1927.

solutions were made from sterile distilled water and sterilized in the autoclave before being used.

Experiments were made with the following: distilled water (pH 6.6), NaOH (pH 7.2, 7.8, 8.0), H_2SO_4 (pH 4.2-5.4), $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$ (pH 7.8-8.6), 0.1 per cent Na_2SO_4 , 0.1 per cent MgSO_4 , 0.001 per cent phenol, 1 per cent peptone, and 0.35 per cent beef extract. In no instance were we able to detect any evidence of a residual germicidal action.

We next added a culture of *Bact. typhosum* to distilled water, sterilized the suspension in an autoclave and irradiated. No residual germicidal effect was noted. Suspensions of the bacteria were then made in sterile distilled water and in sterile 0.8 per cent saline and immediately irradiated. An exposure of two minutes was sufficient to kill all the bacteria even when a suspension of noticeable turbidity was used. Longer exposures were also used. The irradiated suspensions were then tested for germicidal activity. It is possible to interpret the data from these experiments as indicative of the presence of germicidal activity but the number of experiments so far completed is insufficient to warrant a definite statement at the present time.

Attempts have also been made to detect some germicidal action of irradiated cholesterol but have not yet been successful.

CONCLUSIONS

Water exposed to ultra-violet light may retain a slight germicidal power which can be detected under certain conditions.

This activity was detected with *Bact. typhosum* and with Friedländer's bacillus but not with *Staph. aureus*.

A limited series of salt solutions was irradiated but no residual action was noted.

Phenol, peptone and meat extract also give negative results.

Bacterial cells killed by exposure to ultra-violet light appeared to exhibit a residual germicidal action but our data are too meagre to warrant any definite statements. Further work on this action is being carried on.

NEW YORK LEADS THE WAY

THE news that Mayor Walker has approved the creation of a Bureau of Nursing in the New York City Health Department, bringing all of the 535 nurses employed in the field and in clinics under one director, is very significant in the administration of public health nursing.

In the book, *Community Health Organization*,¹ which was the culmination of the revised plans for health department administration, the following recommendation is made in relation to bureaus of nursing in big city health departments:

It is considered essential to the highest efficiency that all the nursing work of the department of health should be organized in a separate bureau and under the direction of a chief who is, herself, a nurse. For the administration of such a large organization as is here provided for, a woman of experience and high natural capacity will be needed, and the salary should be commensurate with those paid to other more responsible bureau chiefs.

It is very gratifying that Amelia H. Grant, R.N., who has had a distinguished career in public health nursing and is recognized as one of the foremost public health nurses in America, has been appointed as Director of the newly created Bureau of Nursing. Her appointment is in accordance with the above suggestion and the best public health procedure of the day.

With the increasing trend of public health nursing from unofficial to official agencies, it is exceedingly important that official agencies consider the best possible means of effective public health nursing within their own organizations.

New York has led the way, and it is to be hoped that other communities will consider seriously the recommendations of *Community Health Organization*, so that they too may develop the best possible administration not only in nursing but in all their divisions.

THE RETIREMENT OF SIR DAWSON WILLIAMS

THE retirement of Sir Dawson Williams as editor of the *British Medical Journal* is a matter of international importance to the medical world. He has served as editor of this great journal for thirty years, and prior to that, had been connected with the editorial department for seventeen years. In other words, for nearly one-half century, his talents and time have been devoted to the service of the medical profession and the advancement of scientific medicine.

We believe the English appreciate this type of work more than Americans. With few exceptions, the tenure of office in this country is comparatively short and uncertain, though there are few professions which require one to keep so constantly abreast of the times and in closer touch with scientific advancement than the editorship of a scientific journal. Not only must one keep abreast of advances, but he must be on guard constantly against pseudo-science as put forward by the faker on the one hand, or the ill-balanced medical enthusiast on the other.

Sir Dawson Williams was the recipient of many honors from scientific bodies as well as from the Crown, and the British Medical Association awarded him its highest honor—the gold medal of merit.

During his term of service, he has maintained the highest standards of the medical profession and has gained distinction as a journalist. We believe that there is no better medical journal in the world than that to which he has devoted the greater part of his life, and of which he was the guiding genius for so many years. We acknowledge our debt to him.

* Since the above editorial was set, we have been advised of the death of Sir Dawson Williams on February 27.

THE MEASUREMENT OF SCHOOL HEALTH PROGRAMS

THE American Child Health Association is engaged in a research study the aim of which is to find out just how successful the public schools of the country have been in promoting the health of their pupils. In other words, it is a study of the effectiveness of school health programs.* This is a research study rather than a survey. A survey tells what is being done and how it is being done. This research seeks the results from what is being done.

The crux of this study is thus measurement—of what is done in the schools, and of the health of the pupils. To a health problem have been applied the principles of educational measurement. It is from the correlation of these two factors, activity and result, that the association

* See September, November and January issues of *Child Health Bulletin*, American Child Health Association.

hopes to find important clues to effective and ineffective school health activities, allowances of course being made for differing external conditions, such as home environment.

Needless to say, the outcome of this study will be watched with the greatest interest. There is nothing so important as the basing of health work, in school and at large, on clear cut evidence of its value—not merely opinions but indisputable factual evidence. Of course, this is a difficult thing to do. Otherwise we should have far more substantial foundations for many health practices than we now have. Public health practice frequently starts from a laboratory discovery of cause and effect. With this premise there is formed a plan for the social application of this knowledge. It is at this point that so many difficulties are encountered. There is a scientific basis for the use of toxin-antitoxin as a protection against diphtheria. Yet, though lessened, diphtheria continues because humanity cannot be induced to apply this knowledge in a thoroughgoing manner.

Even more difficult than the protection against diphtheria is the successful transmission to the public of a general knowledge of hygiene. Here the matter becomes involved with principles of education, psychology and economics.

Now that we have succeeded in eliminating many of those causes of sickness which were open to attack by collective or community action, such as the prevention of typhoid by water purification, and the prevention of malaria by draining away water which favored the propagation of the malaria bearing mosquitoes, the remaining health problems are largely matters of instructing people in personal habits and conduct. The methods of imparting this instruction are of utmost importance. Our only safeguard against ineffectual methods is through frequent checking or measuring of results.

As we all know, school health work has expanded widely during the last twenty years. It is now almost a universal practice for schools to have physical examinations or inspections, nursing service, health teaching, and physical training. The usual reports of the number of examinations, the number of nursing visits, and the number of teeth cleaned, are of interest in illustrating the volume of effort expended.

The great questions which we should all like to have answered, however, are these:

Is the school child who has received this attention within the school, other influences being equal or equalized, a healthier child as a result of this effort?

What particular health activities bring desired results? Does the member of the tooth brush drill class give evidence of a healthier mouth? Is the recipient of routine school medical inspection and nursing service less encumbered by defects? Does the

recipient of a well formulated health instruction program have a better working knowledge of health?

These are facts about which we know too little, and yet which we ought to take steps to know with more certainty if we are to keep faith with the public which is supporting health work. If the association succeeds in clarifying our knowledge it will have done a most welcome service.

Among the many meritorious features of this research there is one thing that deserves particular mention, and that is that a year and a half was spent in preparation before the actual gathering of data in the field. Tests were constructed, tried out and standardized before acceptance. This practice of thorough and considered preparation before launching an extended investigation could well be emulated.

THE CAUSE OF YELLOW FEVER

ANOTHER chapter concerning yellow fever has been written, and the etiology of the disease has at last been cleared of some of its accumulated rubbish. The work of Carlos Finlay and of the Commission under Walter Reed, concerning the agency of the *Aedes aegypti* as the carrier, has been abundantly confirmed, and it seems equally certain that the germ of the disease belongs to the class of filterable viruses, which will pass through the V and N grades of Berkefeld filters.

This work has been done under the auspices of the International Health Division of the Rockefeller Foundation on the Gold Coast of West Africa. The title of the preliminary paper¹ does not give a fair idea of the importance of the contribution. The finding of an animal, the *Macacus rhesus*, which is susceptible to yellow fever, is necessarily a great step forward in the study of the disease, though other facts of equal or greater value, in our opinion, have been proved.

The virus has been carried from monkey to monkey by inoculations of blood or serum 30 times, and by infected mosquitoes 22 times. Mosquitoes fed on infected monkeys on the second or third day of fever invariably acquire the power to transmit the disease. Certain experiments showed that the mosquito remains infective as long as 91 days. Generally the mosquitoes are kept alive easily for the 3 months and are infective as long as they live. It is impractical to carry the virus in monkeys, since it disappears rapidly from the circulating blood, an observation which agrees entirely with that on human beings by the Reed Commission. Many cultures have been made from the blood of infected monkeys in the special media devised for the cultivation of leptospiras, all negative, and so far none have been found in the tissues

of monkeys dead of the disease. We may therefore dismiss the alleged discovery of Noguchi.

It will be remembered that the well-known expert on yellow fever, John Guit ras, never accepted this work, giving two grounds which he considered sufficient for its rejection. The first was that yellow fever did not occur in epidemic form in animals in the tropics, although inoculation with the leptospira was easy, and second that the leptospira was found after the third day, an observation entirely at variance with the proof given by Reed and his associates that the blood of yellow fever patients contained the virus only during the first three days.

The diagnosis of yellow fever, even in its mild forms, seems to be easy by the inoculation of the *Macacus rhesus*, but of almost greater importance is the fact that 0.1 c. c. of the serum from a convalescent patient protected monkeys against fatal doses of virulent blood as well as against the bite of infected mosquitoes.

Once again intensive investigation has revealed the secrets of one of the most puzzling of all diseases, but another life has been given to this discovery. Dr. Adrian Stokes, head of the Commission, fell a victim to yellow fever, contracted apparently from an infective monkey. One other name must be added to the roll of those heroes who have sacrificed their lives for the good of their fellowmen in the course of medical progress.

ASSOCIATION NEWS

CHICAGO MEETING

THE President has appointed Dr. Louis E. Schmidt, Chairman of the Local Committee for the Fifty-Seventh Annual Meeting of the A. P. H. A. Arthur E. Gorman is Secretary of the committee, which is being rapidly completed. Headquarters of the committee have been established in Room 409 of the Hotel Stevens. This office also serves as headquarters for Dr. C. St. Clair Drake, Director of Exhibits. Members of the Association are invited to make full use of the facilities of this office when they are in Chicago.

The Central Program Committee has outlined a program for the Annual Meeting covering 30 sessions of the sections, 7 of them joint sessions. Three special sessions, 2 general sessions, and a banquet are planned in addition. The committee decided to hold the opening General Session on Monday evening, October 15, and begin the section meetings on Tuesday morning. The American Child Health Association, the American Social Hygiene Association and other organizations and committees will hold meetings on Monday. A full program of trips and entertainment is being developed by the Local Committee which is determined to make the Chicago meeting the best the Association has ever held. All meetings will be held in the Hotel Stevens which will be headquarters. Because of the increased attendance which is expected, the Technical Exhibit will be larger than formerly and will include a wider range of interesting displays. A similar extension of the scientific exhibit is planned.

Members who contemplate offering papers at this meeting are urged to communicate without delay with their re-

spective section chairmen, as the programs are rapidly being completed.

RURAL HEALTH EDUCATION

AT the request of the Milbank Memorial Fund the Association has agreed to undertake a share of the direction and organization of a program of health education in connection with the Chautauqua program in about 200 communities in the northeastern United States. A committee has been authorized by the Executive Board to represent the Association in this project, and Dr. S. J. Crumbine has been appointed chairman of this committee. Under its direction data on public health will be assembled for the use of the Chautauqua lecturers who will speak on the importance of personal hygiene and the value of giving generous support to official public health work. The health officers of the states concerned have been invited to meet with the committee to suggest points of emphasis that will be helpful to them in developing the program in their respective states. To assist in this work the Association has secured the temporary services of Dr. Edward T. Devine who will work under the direction of the committee.

WHAT IS PUBLIC HEALTH WORK?

THE first task of the committee authorized to conduct a census of public health workers was to decide on a definition of public health work. It has tentatively adopted the following definition with a series of sub-definitions for public health workers of various types: "For the purpose of this census public health work shall be defined as those activities carried on by an individual himself, or in connection with an organ-

ization, supported either by public or private funds; this work to be directed primarily towards the prevention and control of disease, the promotion of hygiene and the prolongation of life rather than the cure of the already sick individual."

WEST COAST

AN organizing committee for the west has been appointed under the chairmanship of Dr. W. C. Hassler, Health Officer of San Francisco. This committee is considering the possibility of holding a regional meeting of the Association in Portland early in June.

1929 MEETING

IN accordance with the policy adopted last year communications have been sent to health officers and chambers of commerce in all the larger cities in the two districts from which the 1929 An-

nual Meeting city is to be selected. These are the Southeastern and Midwestern Districts.

POCKET CARDS

AT the request of a number of members pocket membership cards have been prepared and will shortly be sent to all members and Fellows in good standing.

WF. Walker, D.P.H., field director of the Committee on Administrative Practice will attend the conference on Records and Reports, Asheville, N. C., April 19-21 called by the Child Health Demonstration Committee.

Elizabeth Brezee, formerly statistician for Child Health Demonstration, Fargo, N. D., will be temporarily associated with the Committee on Administrative Practice, in developing a hospital survey schedule.

NEW MEMBERS

- Robert Eaton Andrews, M.D., Chicopee Falls, Mass. (Assoc.)
- J. W. Becker, St. Louis, Mo., Executive Secretary, Missouri Tuberculosis Association
- Howard H. Bell, M.D., St. Louis, Mo., Tuberculosis Controller
- L. C. Billings, Grand Rapids, Mich., Superintendent and Chief Chemist, Filtration Plant
- Grover C. Bolin, M.D., Orangeburg, S.C., County Health Officer
- R. E. Bower, M.D., Chillicothe, O., County Health Commissioner

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Typhoid Fever Carriers—There are now 155 known typhoid fever carriers in upstate New York exclusive of the 33 who live in state institutions. During the year 1927, 25 newly discovered typhoid fever carriers were added to the list by the New York State Health Department, giving the total mentioned above. These new carriers were responsible for 47 known cases of typhoid fever. Eight of the carriers are male and 17 female, their ages ranging from 21 to 66. One carrier had typhoid fever as long ago as 1871 and 4 of them stated that they had never had typhoid fever. Eleven carriers were removed from the active list during the year. Of these, 4 died, 3 were apparently cured by gall bladder operations, 3 moved outside of New York State, and in 1 the diagnosis was changed.—*Health News*, New York State Department of Health, V, 30, Feb. 20, 1928.

Diphtheria Control in Kansas—

A review of the incidence of diphtheria in Kansas shows no downward tendency has been observed until the year 1922. Kinniman gives 6 reasons for this change: (1) The establishment of full-time county health units in the state; (2) culturing of schools and removal of carriers where epidemics occur; (3) medical inspection of school children and correction of remedial defects of the nose and throat; (4) change in the quarantine laws on cases and carriers; (5) education of the public in preventive measures; (6) immunization of children with toxin-antitoxin.

Educational campaigns with respect to the value of using toxin-antitoxin have been extensively carried on with

the coöperation of newspapers, insurance companies, and 22 county medical societies. This work is resulting in a lower death rate for 1927 than that for 1926. C. H. Kinniman, Diphtheria Control in Kansas, *Kansas Medical Society J.*, 27:325 (Oct.), 1927.

Diagnosis of Measles—Stimson makes a plea for the individual isolation of every person with measles. He feels that secondary infections at times are almost as contagious as is the primary measles. The features of the period of onset are enumerated chronologically by associating them with the fingers of the outspread hand.

Beginning with the little finger is the first symptom, fever. Twelve hours later comes the ring finger, or puffiness of the lower eyelid, and perhaps the measles line, together with the first sign of the enanthem or rash on the fauces. Twelve hours later or middle finger, come the evidences of catarrh, also known as the three C's; to wit, conjunctivitis, coryza and cough. Twelve hours later, or the forefinger, are found Koplik's spots. Thirty-six hours later, or as far from the forefinger to the thumb as it is from the little finger to the forefinger, comes the rash or exanthem, and for the palm we have a certain amount of headache and a considerable malaise throughout this period.

Stimson describes the so-called measles line, "a fairly definite line of congestion across each lower lid, about at the margin of the tarsal cartilage and perhaps a third of the way from the lid margin to the fornix." The appearance of this line has assisted in making an early diagnosis.—Philip Moen Stimson, *The Earlier Diagnosis of Measles*, *J. A. M. A.*, 90:660 (Mar. 3), 1928.

Cattaraugus County Demonstration—The County Board of Super-

visors has voted to finance the activities of the County Board of Health for the year 1928 as developed with the aid of the local demonstration being conducted by the Milbank Memorial Fund. During the 5-year period of the demonstration the tuberculosis death rate has been reduced about one-third, while there has been a reduction of nearly one-fifth in the infant mortality rate. Cataugaus can boast of having established the first county health department and the first county-wide school health unit in New York State. While there have been some objections made to the demonstration program by members of the medical society, it must be said that, on the whole, the physicians have given splendid coöperation in the development of the County Health Department, and have assisted in building up preventive programs in the field of tuberculosis, maternal hygiene, and child welfare.—Edward W. Sheldon, *Milbank Memorial Fund Quarterly Bulletin*, Jan., 1928.

Isolation of Communicable Diseases—The New York City Department of Health has recently distributed new rules for isolation and exclusion of school children in cases of communicable diseases. The small publication in which these regulations appear summarizes a few of the principal signs and symptoms for each communicable disease. There is also an abbreviated statement of the chief source of infection and the mode of transmission. The usual incubation period is stated, and definite rules are enumerated with respect to the duration of exclusion from school for both patient and exposures. The exposures are again subdivided into those having had the disease and those who have not had the disease.

In the case of diphtheria the patient is excluded from school until two successive negative cultures taken not less than 24 hours apart have been obtained from the site of the disease or prefer-

ably from the nose and throat, the first of these terminating cultures to be submitted not less than 12 days after the onset of the disease. Exposed persons may return to school 7 days after the last contact with the patient, provided they show a negative culture at the end of the 7-day period. Those who change their addresses must move to a home where there are no children. All exposed persons are urged to receive temporary protection by an injection of antitoxin. Later they should procure permanent protection by immunization with toxin-antitoxin.

In the case of scarlet fever the patient is excluded for a minimum period of 30 days from onset, provided no abnormal discharges are present at the end of that period. Those exposures who have had the disease may return to school provided they move to a home where there are no children, but those exposures who have not had the disease may return to school 7 days after last exposure.

In the case of measles the patient is excluded from school for 7 days after the appearance of the rash, provided no abnormal mucous membrane discharge is present. Those exposures who have had the disease are not excluded if there is sufficient evidence that they have actually had measles, and if they move to a new address where there are no children. Those who have not had measles may return to school 14 days after the last exposure.

Other diseases for which rules have been outlined are typhoid fever, smallpox, poliomyelitis, epidemic cerebrospinal meningitis, whooping cough, german measles, mumps, chicken pox, and tuberculosis.—Louis I. Harris, Commissioner, New York City Department of Health.

Trachoma Prevention Program—The first organized trachoma prevention work of the U. S. Public Health Service was undertaken in Kentucky in 1912.

In 1913 and 1914 this work was extended to 23 counties in that state, involving an examination of over 18,000 people. A plan was evolved for the establishment of small hospitals to serve as dispensaries and clinic centers, and headquarters for surveys and educational work. The first hospitals were established in Kentucky in 1913. The survey work has been extended to West Virginia, Tennessee, Arkansas and Missouri. In the latter state it was found that 20 per cent of blind pensioners who were receiving on the average of \$300 each per year from the state were blind as a result of trachoma.

The trachoma prevention program has served as an impetus to the installation of full-time county health departments. The trachoma hospitals have a fourfold function:

1. Clinical treatment of cases
2. Study of the disease itself
3. Education of patients in personal hygiene and disease prevention
4. Centers for field work.

Paul D. Mossman, Trachoma In The State's Health Program, *Pub. Health Rep.*, 43:449 (Feb. 24), 1928.

Codification of Ordinances—Greenman aims to suggest a practical manual of procedure for the codification of ordinances. The author points out the need of a systematic code as a convenience to the courts, the legislature, and the city officials. The material codified should be kept up to date and should consist only of those ordinances and regulations which are being enforced, and those which are either obsolete or which have been nullified by changed

conditions should be eliminated. He outlines the administrative code now employed in several cities including Cincinnati, Kansas City, Cleveland, and Toledo, and then proceeds to the establishment of first, a summary outline for a model municipal code, and follows this with a more detailed outline. With regard to the sanitary code the author states:

Sanitary codes applicable to various sections of the country are more difficult to standardize. They must be developed in conformity with state-wide conditions. Model sanitary codes have been prepared for some states, notably New York and Iowa. The American Public Health Association has a model sanitary code in preparation at the present time. The U. S. Public Health Service has issued bulletins giving municipal ordinance rules and regulations pertaining to public health. These bulletins will often give sanitary regulations on special subjects and are of considerable value where unusual conditions are being regulated.

The model sanitary code contains 7 articles, each one of which has from 2 to 37 subdivisions. The articles are as follows:

1. Communicable diseases
2. Milk and cream
3. Meat and meat products
4. Sanitation
5. Camps
6. Miscellaneous
7. Penalties and general provisions.

The captions of the subdivisions serve to remind one working on a proposed sanitary code of the practices and procedures which should be considered in formulating such code.—E. D. Greenman, Codification of Ordinances, *Publication No. 6*, Municipal Administration Service, 261 Broadway, New York, N. Y., 1928.

LABORATORY

C. C. YOUNG

A SIMPLIFIED PROCEDURE IN DETERMINING B. COLI IN WATER

(PRESUMPTIVE TEST)

WILLIAM LITTERER, PH.C., M.D.

*Director of Laboratories, Tennessee State Department of Public Health,
Nashville, Tenn.*

SIMPLIFICATION of any procedure in determining *B. Coli* in water is manifestly welcomed by bacteriologists provided it does not jeopardize accuracy in attaining results.

This procedure is not only simple but quite inexpensive as compared with the Smith fermentation tube or the Durham inverted tube method in determining the production of gas in the lactose broth medium.

This method has been used by the Tennessee State Department of Public Health Laboratories for a number of years with a few modifications each year

until at the present time the following procedure is being carried out.

Instead of using the Smith fermentation tube or the Durham tube we simply employ an ordinary specimen bottle, capacity 50 c.c.; outside diameter at the base 4.3 cm.; outside diameter at the mouth with lip 4 cm.; height 8 cm. Into this specimen bottle a test tube is inverted, capacity 10 c.c., length 10 cm.; outside diameter 1 cm. A tin salve box (lacquered) which is ordinarily used in mailing samples of feces, is used for a covering or top to fit over the mouth of the bottle (either the top or bottom

Five samples of water can be tested in this compact space

| 4 Test tube with cotton string | 9 Fermentation bottle and tube indicating fermentation |
| 5 Test tube pushed into hole of tin top with cotton string on under surface | |

of the box can be used). This tin box should have an inside diameter slightly greater than the outside diameter of the mouth of the bottle so as to fit loosely over its mouth. The tin top should have a hole cut into its center so that the test tube will fit snugly when pushed into it. The diameter of the hole should be about the same as the outside diameter of the test tube. It is necessary to make the joint fit securely to prevent outside contamination. This is accomplished by wrapping a cotton string (wet) 2 or 3 times around the test tube at a point on a level with the mouth of the bottle. Then the tin box is pushed down over this which acts as a washer. It will fit securely especially after sterilization which causes the cotton string to contract thereby making a perfect joint. The cotton string serves to hold securely the tin top to the test tube and at the same time to prevent outside contamination. Quite recently we have used an improvised method of fixing the top to the test tube; viz: by soldering a small galvanized iron ring, 1 cm. on the under surface of the tin box. The ring should have sufficient diameter to allow the cotton string to act as a bushing. This soldered ring on the under surface of the tin box serves to fit the test tube in a definite position and affords a better bushing with the cotton string. However, the other method is practically as satisfactory. The tin top overhangs the mouth of the bottle about 1 cm. which also prevents dust particles and bacteria from gaining entrance to the bottle.

This simple apparatus, above described, is now ready for use. About 30 c.c. to 35 c.c. of lactose broth is introduced and sterilized on 3 successive days or by autoclave 15 lbs. not to exceed 20 minutes. Such sterilization will dispel all of the air in the inverted test tube leaving no bubbles in the upper part. Such an apparatus, which we may term as a "fermentation bottle," is quite inexpensive only costing about 5 cents. It is

easy to clean and to refill, not apt to break—will set on its own base and there is no cotton to contend with.

Another great advantage is the rapidity with which water can be inoculated in this "fermentation bottle." For

Tray holding forty sterile "fermentation bottles" filled with lactose broth ready to be tested.

example, if 10 c.c. of a given water is desired to be inoculated into a "fermentation bottle," just simply raise or tilt, with the left hand, the test tube attached to the tin box and with the right hand introduce the 10 c.c. of water by means of a 10 c.c. pipette. Many samples can in this way be inoculated in a very short space of time.

SPECIAL TRAY

Another advantage is the great saving of incubator space especially where a large number of samples of water is to be examined, viz: by the use of a "special tray" which we have devised for the purpose. This tray is designed to fit the average regulation incubator. It is sufficiently large to hold 10 samples of water. These trays can be placed upon each other so that 20 or even 30 samples of water can be tested for fermentation in any regulation small incubator.

The tray can be made by a carpenter at a very small cost. The following are the dimensions of a tray that will hold enough "fermentation bottles" to analyze at one time 10 samples of water. We

use 8 "fermentation bottles" as a routine for each sample of water for example:

5 bottles	containing	10 c.c.	of the water
1 "	"	1 c.c.	" " "
1 "	"	1/2 c.c.	" " "
1 "	"	1/10 c.c.	" " "

Therefore for 10 samples of water there will be 80 "fermentation bottles."

The tray is made of poplar wood about 2 cm. thick. It is 43 cm. long, inside dimension, and 34 cm. wide, inside dimension. The border or flange of the tray should be raised about 2.5 cm.

On the outside of the tray are the following numbers printed on the flange of the long portion 43 cm., viz: 1, 2, 3, 4, 5, 6, 7, 8, 9, 10; This indicates the number of samples of water to be tested. Now on the wide or short side of the tray, i.e. 34 cm. is printed 0.1 c.c. —0.5 c.c. —0.1 c.c. —10 c.c. —10 c.c. —10 c.c. —10 c.c. —10 c.c. This indicates the amount of water inoculated into the "fermentation bottles." If you prefer to change the figures as to the quantity of water introduced into the "fermentation

bottles" you may do so according to your preference. We simply use this amount as our routine examination of all samples of water where we have a reasonable check on said waters. However, on totally unknown waters we employ a greater dilution in addition to the above scheme outlined.

The tray containing 80 bottles (10 samples of water) can now be easily handled and placed into any regulation incubator. At the end of 24 hours it can be removed and fermentation noted. If any of the tubes show fermentation then a sterile platinum loop is thrust into the "fermentation bottle" by simply lifting and tilting the test tube and attached tin top. No cotton to worry with or flaming the mouth is necessary. No removal or handling of the "fermentation bottle" from its original position. It is not necessary to remove the bottle from the tray. The tray is now placed back into the incubator for another 24 hours and at the expiration of 48 hours a final reading of the various fermenting tubes is re-

Tray holding eighty sterile "fermentation bottles" filled with lactose broth ready to be tested. Ten samples of water can be tested in this compact space.

corded or subsequently inoculated on Endo media, etc., etc., for final determination of *B. Coli*. The suspicious colonies isolated on Endo or litmus lactose agar or E. M. B. media can now be inoculated into a sterile "fermentation bottle" containing lactose broth or other sugars if necessary.

If a tray is wanted to hold enough for the examination of 5 samples of water or in other words to hold 40 "fermentation bottles," the following inside dimensions are recommended, viz: 34 cm. long, and 22 cm. wide, with a flange about 2.5 cm. from inside.

WATER ANALYSIS IN THE FIELD

The use of the "special tray" for 5 samples of water holding 40 sterile "fermentation bottles" filled with lactose

broth renders possible the inoculation of water samples in the field. An ordinary hand valise will hold 2 of these trays, i.e. enough material for the examination of 10 samples of water. Owing to its compactness there is no danger of spilling the media unless the valise be actually up-ended. The sterile pipettes can also be placed in the valise hence making the outfit complete. The inoculated samples can now be taken to the nearest incubator for future observation.

CONCLUSION

The foregoing outlined procedure is practical and accurate, at the same time inexpensive and time saving. It should appeal to all laboratories especially to state laboratories where a large number of samples of water is daily examined.

VITAL STATISTICS

LOUIS I. DUBLIN, PH. D.

A New Health Record in American and Canadian Industrial Populations—In no previous year were health conditions among the industrial populations of the United States and Canada as satisfactory as during 1927.

The death rate among the wage-earners of the two countries, and their dependents, may be accurately gauged by that of the more than 18 million of them who are industrial policyholders of the Metropolitan Life Insurance Company. This rate dropped, in 1927, to the amazingly low figure of 8.4 per 1,000, which is a new minimum for all time. The year 1926 is the latest for which comparable mortality data for the general population are available. From 1911 to 1926 the general population death rate for persons in the age range which is comparable with that of the Metro-

politan industrial experience (that is 1 to 74 years, inclusive) declined only 11.7 per cent. But among the insured wage-earners, their wives and children, during the same period of years, the death rate dropped 29.3 per cent. The reduction in the death rate has been reflected in a considerable increase in the expectation of life. Among wage-workers and their families the expectation of life in 1926 was 8.39 years longer than the average for the years 1911 and 1912. In the general population the increase was only 4.70 years.

There were very few untoward developments in the public health record of the year. There were, it is true, some unfavorable items, and these are of considerable importance because they pertain to preventable diseases. Early in the year there was a bad outbreak of

typhoid fever in Montreal; and there was unusual prevalence of poliomyelitis in the United States which resulted in an above-average death rate for this disease. The year was also marked by an increase in the prevalence of diphtheria, which was not only quite general over the United States but in various other parts of the world. What has happened with reference to these three diseases has had little effect upon the general death rate because, after all, they are of relatively small importance numerically. More important is the increase in violent deaths.

Beyond question the greatest single public health fact of 1927 was the great reduction in mortality from tuberculosis to a new minimum for all time. The death rate from tuberculosis of the respiratory system which causes almost nine-tenths of all the deaths from tuberculous disease, has dropped 59.3 per cent since 1911. While the mortality from diphtheria increased slightly last year there was marked improvement with respect to measles, scarlet fever, and whooping cough. No other single item contributed so much to the establishment of a new minimal death rate last year as did the unprecedentedly low mortality from pneumonia. And never before except in 1919 and 1921 (the years following the great influenza pandemics) has there been as big a year-to-year drop in the pneumonia death rate as was recorded between 1926 and 1927. A drop in the mortality from influenza was an important factor in establishing the new minimum for pneumonia. The facts for cancer in 1927 give no comfort. Although the death rate is only fractionally higher than that for last year it again stands as a new maximum figure for this disease. The diabetes death rate in the industrial population in 1927 was the same as in 1926. The death rates for heart conditions and cerebral hemorrhage dropped slightly last year and that for chronic nephritis declined appreci-

ably. The death rate for puerperal diseases, in 1927, although identical with that recorded in 1926, is the lowest ever registered among women in the American and Canadian industrial populations. The 1927 alcoholism rate was higher than that for any year since 1917 with the exception of 1926. It is lower than for any year between 1911 and 1917 inclusive. There was a slight decline in the death rate, from cirrhosis of the liver, that is, from 6.7 in 1926 to 6.6 in 1927. There is one single item in the fatal accident situation where conditions are going from bad to worse each year. This item is automobile fatalities. The 1927 figure is more than eight times that for 1911, more than three times that for 1915, almost twice that for 1917 and has increased 67.6 per cent in the 7 years since 1920. The 1927 suicide rate was the highest in the industrial population since 1917. The homicide rate showed a slight increase over last year.—*Met. Life Ins. Co. Stat. Bull.*, 9:1-9 (Jan.), 1928.

Vital Statistics of Philadelphia, 1927—The death rate in Philadelphia was 12.2 per 1,000 population, the lowest in the history of the city. The only other year which approached that of last year was 1921, when the general mortality was 12.7. The greatest reductions are in the acute and chronic infectious diseases. A conspicuous feature is the tremendous drop in the mortality from pneumonia and broncho-pneumonia. Last year the total number of deaths from these two causes was 2,361 and a mortality rate of 116.0 per 100,000 population, compared with 3,441 and a mortality rate of 171.4 for the year 1926. The tuberculosis death rate for the year 1927 (85.5 per 100,000 population), as well as the infant mortality (63.8 per 1,000 births), were the lowest in the history of the city.

The common acute infectious diseases showed the lowest mortality on record;

typhoid fever with a death rate of 1.4 per 100,000 population; measles with only 3 deaths and a rate of 0.2; scarlet fever, in spite of its prevalence, registered only 34 deaths and a rate of 1.7; whooping cough with 31 deaths and a rate of 1.5; diphtheria with 220 deaths and a rate of 10.8, which was the lowest on record. There were 1,175 fewer deaths from heart disease last year than in 1926.—Philadelphia Dept. of Public Health. *Monthly Bull.* 13:2, (Jan. & Feb.), 1928.

Vital Statistics of Kenya, British East Africa—The compilation of vital statistics in Kenya is made difficult by the lack of definite information as to the number of natives living in the section and by poor registration of births and deaths.

In Nairobi a census in 1926 showed 2,665 Europeans and 9,199 Indians, Arabs and others while the Africans were estimated at 21,000 making a total of 32,864. The total deaths in 1926 were 745 giving a crude death rate of 22.6 per 1,000 as compared with 12.8 for 1925. The European death rate was 13.5 per 1,000 Europeans, the Asiatics had a rate of 30.3 and the natives 17.3. The chief cause of death was pneumonia which caused 171 deaths in 1926, and 121 in 1925, malaria caused 130 deaths in 1926 and 19 in 1925, plague 32 in 1926 and 4 in 1925, tuberculosis 17 in 1926 and 14 in 1925, dysentery 9 and typhoid fever 4 in 1926.

The population of Mombasa was 40,500 including 676 Europeans. There were 776 deaths in 1926 giving a death rate of 19.5 for the total population and of 13.3 for the Europeans. Pneumonia caused 150 deaths in 1926 and 105 in 1925, pulmonary tuberculosis 69 deaths in 1926 and 67 in 1925, malaria 84 in 1926 and .93 in 1925, diarrhea and dysentery 45 in 1926 and 87 in 1925.

The population of Kisumu in 1926 was 7,656 including 141 Europeans. In

the same year there were 191 deaths giving a death rate of 24.9 as compared with 17.9 in 1925 and 1924. The European death rate in 1926 was 21.3. The death rate from respiratory diseases was 850 per 100,000 in both 1925 and 1926, from tuberculosis 50 in 1925 and 90 in 1926, from malaria and blackwater fever 100 in 1925 and 380 in 1926, and from intestinal diseases 200 in 1925 and 340 in 1926.—*Annual Medical Report of the Colony and Protectorate of Kenya*. 1926. p. 9-18.

Health Conditions in Tanganyika—From a report to the League of Nations on the administration of Tanganyika territory for the year 1926, it appears that the European population is now about 4200. The total native population is now estimated as 4,319,000.

The number of European medical officers employed increased from 39 in 1925 to 46 at the end of 1926, the number of Asiatic assistant, senior sub-assistant, and sub-assistant surgeons from 39 to 50, and the number of private doctors registered as medical practitioners in the territory from 8 to 14. These figures do not include the headquarter staff, laboratory staff, entomologist, and dental surgeons.

The incidence of dangerous infectious diseases throughout the territory during 1926 was very low. A total of 20 cases of smallpox was reported from five districts; no deaths occurred. Cerebrospinal fever showed no signs of becoming epidemic; only light cases, with 4 deaths, occurred.

With the exception of 6 fatal cases reported from the remote district of Shirati, an epidemic area situated on the Tanganyika-Kenya border, no cases of plague were reported in the whole of the territory. Influenza, as in previous years, has been responsible for the largest number of deaths—viz., 209—the number of cases is not known.

During the year 6 medical officers have been seconded exclusively for sleeping sickness work. No new foci of infection have been discovered, and the activities of the sleeping sickness staff have been mainly concentrated on the infected areas in the Tabora and Ufipa districts. The policy adopted in this enormous area, approximately 10,000 square miles in extent, has been to concentrate the population in fly-free clearings. The disease shows no sign of becoming endemic, and until the fly can be eliminated, or the inhabitants removed to fly-free areas, sporadic cases will continue to occur.—*Lancet* 2:1219-1220 (Dec. 3,), 1927.

Health of Northern Ireland, 1926—The fifth annual report of the Registrar-General relating to Northern Ireland in 1926 gives the number of inhabitants of Northern Ireland as 1,256,322. The birth rate fell steadily from 1920, with the exception of 1923 and 1926, in which years there were slight recoveries. The death rate has varied considerably; it was high during the war years, and then fell steadily until, in 1923, it reached 14.9. In the following year an epidemic of influenza and a high rate for respiratory diseases resulted in an increase to 16.1, but since then there has been an annual decrease, and the rate of 15.0 for 1926 is the lowest recorded during the past 10 years, with the exception of that registered for 1923. Deaths from tuberculosis continued to decrease, but still represent nearly 10 per cent of the mortality from all causes. In the age period 15 to 25 this disease is responsible for over 54 per cent of deaths, whereas in the following 10-year period the proportion falls to 44 per cent. Deaths from influenza in 1926 totalled 482, being less than half the average for the past 10 years.

Heart disease was the chief cause of death, and is followed by tuberculosis and cancer; the death rate from this last

condition has risen each year from 1922 to 1925, but was slightly lower in 1926. There was a slight increase in the mortality due to encephalitis lethargica and cirrhosis of the liver.—*Brit. M. J.* Jan. 7, 1928, p. 29.

Health Conditions in New York State, 1927—The health of the people of the State of New York in 1927 was exceptionally good. The death rate (12.3 per 1,000 population) was never lower and was equalled but once in 43 years. Infant mortality (59 deaths under one year per 1,000 live births) was the lowest recorded since 1904, when these deaths were first compiled separately. The birth rate (19.9) was practically identical with that of 1926.

There was a drop in the death rate from diseases of the heart. We must not, however, ascribe too much significance to this decline because the high death rate in 1926 was directly influenced by the abnormally severe weather during the first months of the year. The present death rate from diseases of the heart, with the single exception of the preceding year, is still greater than ever before. The death rate from pneumonia (107.2 in 1927) declined 28 per cent and the proportion of deaths due to this cause was only 8.7 as compared with 11.1 in 100 deaths last year. The death rate from pneumonia in 1927 was, with one exception, the lowest ever recorded. Cancer, with the highest mortality (124.3) on record, is now second among the causes of death. A year ago it was third, in 1917 it was fifth, and 20 years ago it was eighth. The death rates from nephritis, acute and chronic, 82.7 and from tuberculosis, all forms, 81.9, have never been lower. The decline in the tuberculosis death rate was the greatest recorded in any one year since 1921 and the 1927 rate was one-half of the rate recorded only 10 years ago.

New minimum points were reached by typhoid fever (1.7), measles (1.6),

diarrhea and enteritis under 2 years, (13.1), bronchitis (5.0). The mortality from whooping cough (4.2) was lower only once since 1885. On the other hand, the continued decline in the death rate from diphtheria was broken with an increase from 6.4 to 8.6. The diabetes death rate (24.4) was practically the same as in 1926, which, next to the rate of 1922, was the highest in 20 years. The death rate from automobile accidents (21.2) continued to rise, the suicide rate (16.0) was the highest since 1915, and the rate from homicide (5.0) was higher but once in a score of years. The mortality from alcoholism (8.1) was identical with that of 1926. Cases of diphtheria increased by almost 7,000 as compared with 1926; there was also an increase of more than 200 cases of poliomyelitis, 13,000 cases of scarlet fever, 5,000 cases of chickenpox, and almost 15,000 cases of mumps.—New York State Dept. of Health. *Health News* 5:25-26 (Feb. 13.), 1928.

Vital Statistics of Great Britain, 1927—The British birth rate of 16.7 per 1,000 is the lowest recorded since the establishment of civil registration. The rate in 1926 was 17.8. The death rate was 12.3 which is 0.7 per 1,000 above that of 1926. The infant mortality rate was 69 per 1,000 births which is equal to the 1923 rate, the lowest on record.—*New York Times*, Jan. 20, 1928.

Rheumatic Fever and Heart Disease in London—Recent estimates indicate that from 40 to 50 per cent of the recorded mortality from heart disease is rheumatic in origin. At early ages this proportion is doubtless considerably greater but the studies that have been made fail to show any clear evidence

that the mortality from heart disease at any particular age period is especially associated with the prevalence of rheumatism in the different areas. Assuming the rheumatic fever mortality rate to be an approximate index of rheumatic prevalence the local incidence of the disease shows a general tendency to be more common in the areas where the conditions of life are least favorable. There is a closer relationship, however, between unfavorable environment and the mortality from heart disease at the early ages in which the majority of the cases are undoubtedly of rheumatic origin. This correlation appears to be practically equivalent at ages 15-24, 25-44, and 45-64 and is generally more intensive than that between the mortality from rheumatic fever and heart disease at any of the corresponding ages. The mortality from cardiac disease in females seems to be more closely related to environmental conditions than in males but it is difficult to decide whether this is due to the more continuous and prolonged exposure of the female population to the deleterious influences of the unhealthy home.

Previous studies have shown a positive correlation in the county divisions of England and Wales between the rheumatic fever mortality and the general prevalence of damp and cold weather as well as with the mortality from organic heart disease. In London, however, perhaps because of more uniform weather conditions, there is smaller variation in the mortality rate from rheumatic fever and a less definite association with the incidence of heart disease.—Matthew Young. *Some Observations on the Mortality from Rheumatic Fever and Heart Disease*—*Lancet*, 2:1069-1070. (Nov. 19), 1927.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C. E.

STUDIES ON THE USE OF CHLORINE IN SEWAGE TREATMENT

H. G. BAITY

University of North Carolina, Chapel Hill, N. C.

IN coöperation with the Chlorine Institute and the town of Chapel Hill, N. C., the Division of Sanitary Engineering of the University of North Carolina has begun a series of studies on the use of chlorine in sewage treatment. The university and town are served by two sewage treatment plants. One plant consists of an overloaded Imhoff tank, located at some distance from town and frequently receiving sewage in a septic condition, which provides only screening and plain sedimentation of the strictly domestic sewage, and discharges it into a small stream of low velocity flowing for a distance of more than four miles below the plant before receiving any tributaries. This plant affords ideal conditions for studying the effects of chlorine on foaming, hydrogen sulphide production, disinfection, reduction of biochemical oxygen demand, sludge digestion, and the progressive oxygen demand down-stream. The other treatment plant, of smaller size, is located nearer the town, receives fresh domestic sewage, and consists of a primary Imhoff tank, lath trickling filters, and secondary Imhoff tank discharging its effluent into a small, but rapidly flowing, brook. This plant is suitable for studies of the effects of chlorination on secondary treatment processes.

The scope of the investigation as at present projected may be summarized

under the following headings:

1. Correction of foaming in Imhoff tanks
2. Study of chlorine demand of raw sewage and tank effluents under different seasonal conditions
3. Effect on plant operation of chlorination of sewage in long outfall line at various distances above treatment works
4. Hydrogen sulphide control in plants
5. Effect on biochemical oxygen demand of effluents by prechlorination and postchlorination
6. Effects of various degrees of chlorination on progressive oxygen demand in water of stream below plant
7. Disinfection efficiency of various amounts of chlorine applied before and after sedimentation in Imhoff tank
8. Effect of chlorination on sludge digestion as indicated by pH, mineralization, quantity and quality of gas production

Recording devices are provided for measuring the flow of sewage and that of the receiving stream. An injector-type chlorinator, housed in a portable building, can be moved to any desired point of chlorine application. The chlorine and chlorine equipment are furnished by the research division of the Chlorine Institute, while the town of Chapel Hill has built the necessary structures, gaging and sampling stations, and assists in the conduct of the work.

These studies have been in progress since the fall of 1927, and will probably be continued for a period of a year, or longer.

The Effects of Storage Upon the Quality of Water—The quality of stream water depends upon the proportion of ground water to run off water present. In dry weather there is proportionately more ground water than surface water in the stream, and proportionately greater quantities of inorganic salts are present. This is conducive to development of algae, which, in the presence of sunlight because of their chlorophyl, are able to combine these salts with dissolved carbon dioxide and thus obtain their food supply.

Ninety-nine per cent of the normal strains of pathogenic bacteria disappear at the end of a week's storage and all of them at the end of a month. Water initially good obtained from an upland source will not be improved much by storage; in fact, a deterioration may result. Water from a larger river will almost invariably be improved.

In general, under these conditions, storage will result in decided decreases in: (1) Concentration of organic and inorganic solids by sedimentation; (2) concentration of organic impurities by precipitation and oxidation; (3) color in upper layers by oxidation and the bleaching action of sunlight; (4) concentration of hardness forming salts due to loss of CO_2 by diffusion, on utilization by plants, and by absorption of these salts by plants and animals during growth; (5) the number of bacteria; by sedimentation, exhaustion of food supplies and utilization as food by other forms of life.—A. Gordon Gutteridge, *Health, Commonwealth of Australia*, 5: 35 (Mar.), 1927. Abstr. L. M. Fisher.

Pressure Filtration Plant—A mechanical filtration plant to remove peat stain and counteract plumbo-solvent action in a portion of the water supply at Bradford, England, is described. The supply is from peat lands containing humic acid. Water must be treated with an alkali to prevent lead poisoning. Sul-

phate of alumina and lime or chalk are added for coagulation, removal of color, and neutralizing the acidity. The chemicals are fed as solution through plunger pumps operated by variable speed direct current motors. The speed is varied automatically with the flow by means of a Venturi meter which actuates a mercurial differential gear which in turn operates a small electrical rheostat.

The decision to adopt mechanical filters in this instance was reached chiefly on account of the following considerations, viz: (a) There is no suitable site on which to erect slow-sand or open gravity filters between the reservoir and the first point of delivery; (b) peaty discoloration can be effectively removed; (c) acidity can be readily neutralized, thus removing or reducing metallic solvency and corrosion; (d) initial cost of construction is less than that of slow-sand filters; (e) contamination from the air and the encouragement of the growth of algae are avoided, as the filtrate is delivered direct to the district of supply; (f) no interruption from frost; and (g) the bacterial purification is as efficient as in slow-sand filtration. The operating and maintenance charges are higher, owing to the cost of the coagulant—sulphate of alumina—used to effect color removal, and the wash water used may be greater, owing to the increased burden on the mechanical filters arising from the decolorization process. But these factors are largely, if not entirely, offset by the interest received on the greatly reduced capital expenditure for the mechanical filters, which entirely remove the peaty stain and give a clear, colorless water.—Anon. *Water Works*, 66:11 (Jan.), 1927. Abstr. E. A. Reinke.

The Standard Milk Ordinance in North Carolina—In 1924, as a result of a preliminary survey, it was found that 21 North Carolina cities had adopted a milk ordinance of some sort and were carrying on control measures. A study of the ordinances brought out very strongly the fact that there existed a great variance in the requirements.

Since it was almost impossible to bring about a uniformity in all the ordinances, the State Board of Health recommended to the cities the U. S. Public Health Service Standard Milk Ordinance. This was done for the following

reasons: (1) Uniform standards of quality were considered to be of basic importance; (2) uniform standards of milk sanitation were advocated; (3) the ordinance was found to be complete, fair, and practical; (4) classification of milk by grades is a sound principle on which to base the establishment of widespread uniformity of milk sanitation standards; (5) it was recognized that the services of an official correlating agency, such as the U. S. Public Health Service, was essential to the widest adoption of uniform, reliable standards.

Of the 21 cities in 1924 that had milk ordinances, 17 have adopted the Standard Milk Ordinance in place of the one they had. In addition, 16 other cities have adopted the Standard Milk Ordinance, thus making a total of 33 having it in effect. Ten cities with populations between 5,000 and 10,000 and 8 cities with populations less than 5,000, have adopted this ordinance.

The main features of the Standard Milk Ordinance are given, together with a discussion of the importance of further safeguarding a high grade raw milk by proper pasteurization, since health authorities are now convinced that no milk can be considered entirely safe in its raw state, no matter how carefully its production is safeguarded.—Malcolm Lewis, *Health Bull.*, North Carolina State Bd. of Health, 42:13 (June), 1927. Abstr. P. R. Carter.

Regarding the Procedure in Sludge Digestion—The process of decomposition in the sludge chamber in the presence of excess and subnormal pressure was investigated. An excess pressure had no influence on the gas production or even on the general decomposition of the organic material. With subnormal pressure, in contrast with the studies of Watson and Watsaws, an increase of the generated gas occurred, evidently on account of the more rapid withdrawal. A more rapid decomposi-

tion of the organic material did not, however, take place under these conditions. In opposition to other authors, light had no effect on the process in the digestion chamber. Phenols in the sewage affected the gas-forming bacteria more unfavorably than the liquefiers. Higher sulphates in the sewage resulted in higher hydrogen sulphide content in the gas. Introduction of oxygen delayed and injured the digestion process, as the rapid development of the hydrogen sulphide oxidizing bacteria was arrested. Sewage containing sulphates delays the decomposition process and in such cases larger digestion tanks are therefore essential. Acid sewage modifies the digestion process, especially by slight changes of the hydrogen ion concentration. The addition of 10 g. of chlorine to 1 cbm. of sewage sterilizes the precipitated sludge so completely that its ability to decompose is practically destroyed. Sodium chloride solutions up to 1 per cent have absolutely no effect on the sludge digestion process; up to 3 per cent it is decreased about 20 per cent. These phenomena are explained by a peptonizing action of the salt on the sewage colloids. Sodium chloride diffuses only slightly in sludge mixtures and also the salt in the sludge diffuses very slowly in the surrounding water. Therefore, the amount of sodium chloride present affects the regular automatic conversion of sludge in the digestion tank. F. Sierp. *Tech. Gemeindebl.* 29, 21-24. Translation of an abstract in *Zentralbl. f. d. ges. Hyg.*, 15:496 (Aug. 10), 1927. Abstr. J. K. Hoskins.

Human Ascaris As a Household Infection—An attempt to shed light upon the etiology of Ascaris infestations from a study made in a section of the Republic of Panama is reported. In the rural areas there, human excrement is not used for fertilizer and the source of drinking water is in most cases free from any possibility of fecal contamination,

yet the *Ascaris* incidence varies from 40 to 90 per cent. The author was able to estimate that the number of ova passed per diem in 8 different households ranged from 2,970,000 to 99,960,000, individual persons varying from negative to 64,760,000. The unique character of this study, however, was the demonstration by a flotation method, of *Ascaris* and *Oxyuris* ova, containing motile embryos, in the sweepings from the dirt floors of the homes and door-yards. This leads to the conclusion that such places "are a source of *Ascaris* infection of considerable importance." It was possible, experimentally, to demonstrate that *Ascaris* ova in feces under typical local conditions would reach the motile embryo stage in 14 days. Harold W. Brown, *J. Parasitol.*, 13:206 (Mar.), 1927. Abstr. N. R. Stoll.

Experience in Destroying Sewage Screenings By Burning—The sewage screening and screenings disposal plant at Long Beach, Calif., is located near a popular bathing beach which necessitated careful designing and required special operating attention to avoid the creation of a nuisance. Details of the plant design and operation are given by the author who was formerly superintendent of the sewage works at Long Beach.

The old plant was remodeled in 1924 and an additional unit built so as to insure continuous operation on a 24-hour basis. The combustion chamber and the ash pit of the new unit are lined with refractory material, and all walls and roof insulated with the same. Gas is used for fuel and a temperature ranging between 1600° F. to 1850° F. is maintained. This temperature was found to be most satisfactory, as higher temperatures produced clinkers hard to dispose of. The rate of burning in the old unit was about 10.5 lb. of screenings per minute, but in the new unit a much greater amount is handled at less than

half the fuel cost. The screenings removed from Long Beach sewage average 30.7 cu. ft. per m.g., but during the canning season (fish and tomatoes), peak loads run as high as 45 cu. ft. The cost of burning the screenings is estimated at \$4.025 per cu. ft., which includes fuel and labor. Although the nearest houses are only 75 ft. from the incinerator stack, no complaints about the operation of the plant have been made.—Robert A. Appleton, *Eng. News-Rec.*, 99:500 (Sept. 29), 1927. Abstr. Ella G. White.

The Disappearance of Typhoid Bacteria in Water—For a study of the reasons for the disappearance of typhoid bacilli in water, water samples from different sources were inoculated with typhoid organisms and stored under similar conditions. The types and numbers of protozoa occurring in the water were also observed. The typhoid bacilli disappeared from tap water, rain water and water from a swimming pool in from 7 to 10 days and their disappearance corresponds with a marked increase of a bacteria-eating protozoon—*Oicomonas termo*, *Cercobodo alexieffii*, *Cyclidium glaucoma*. With ground water the result was less marked. In one of the experiments, the bacilli disappeared only after 4 weeks in spite of the presence of the same protozoa; in another they were not present after 13 days, while in water from the same source that had been freed from protozoa by filtration they remained 4 days longer. It is concluded that at present unknown factors other than bacteria-eating protozoa are also responsible for the disappearance of the typhoid organisms.—N. L. Wibaut and Isebree Moens, *Verslag d. afdeel. Natuurkunde koninkl. akad. v. Wetensch.*, 36:129. Translation of abstract *Zentralbl. f. d. ges. Hyg.*, 15: 486 (Aug. 10), 1927. Abstr. J. K. Hoskins.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D. AND LEONARD GREENBURG, PH.D.

Health of Office Workers—According to the federal census in this country in 1920 there were about 3,100,000 persons engaged in clerical work, but interest in their health matters has lagged behind that of the regular industries. Ramazzini in 1713 remarked upon the maladies of clerks who were mostly males in those days; and Thachrah reëmphasized the same in 1831. Today the members of most clerical groups are predominately feminine and unmarried, young rather than middle aged or aged, city or town dwellers, and they may present a selection of persons physically substandard. According to the census, in two large groups, "other clerks," and "stenographers and typewriters," over 51 per cent of both sexes were in the age group 15 to 24 years, and of females, 61 per cent. Tuberculosis of the lungs caused 46 per cent of the deaths in this young age group, with heart disease, Bright's disease, accidental violence and pneumonia, following in the order named. The mortality in this group for tuberculosis was 170.7—highest for all occupational groups. (The paper then discusses in detail various statistics based upon the census and especially the data available in the Home Office of the Metropolitan Life Insurance Company.) In general, females are not only more frequently absent but lose more days from sickness than males, thus, in 1925 males lost 8.82 working days, females 12.44, or 141 per cent of the male rate. However, men averaged 7.08 days absence and women only 4.41 days. Among males there were 1.246 cases of absence per clerk-year; among

females 2.824, or 226 per cent of the male rate. A most interesting feature of this study was that sick absence varies quite directly with age; that is, a woman of 25 will in all likelihood have a worse sickness absence record than one of 20.

Distribution of sickness by departments in the organization, of which there were 188, showed that the worst had an experience about 65 times that of the best! Of little importance is consideration of causes of sick absence and it is recommended that the *International List of Causes of Death* be used as a basis for a standard nomenclature in dispensary practice. Of illnesses causing absence among males and females combined over 38 per cent were due to respiratory diseases; 27 per cent to diseases of the digestive tract; and over 11 per cent of the cases among females to dysmenorrhea. Sickness calls in the Metropolitan employes during 1925 and 1926 total more than 150,000, mostly, of course, unattended by absence. The curve of absenteeism drops in mid-summer, rises in the fall, drops slightly in early winter, and then rises in a late winter peak. There are two separate types of colds, one of the fall type, the other occurring in mid-winter; there is also a strong suggestion of a relation between a drop in the mean temperature and an increase in colds. This is contrary to a warmer climate such as California, where the incidence of colds varies greatly without marked change in temperature. (The various afflictions of clerical workers are discussed in detail with accompanying tables and graphs.) "Employers of clerical workers cannot

ignore the importance of the problem of time and efficiency lost through disease and it is almost inevitable that they share with their employes the burden of maintaining some mechanism for the relief and control of the situation. The problem is not so much the reduction of sick absenteeism to the lowest possible limit as it is the maintenance of the healthiest possible group of workers."—Wade Wright, *Proceedings of the Convention, The Life Office Management Association (Metropolitan Life Insurance Company)*, Oct., 1927, 35 pp.

Toxic Risks of Spray Painting—At the third conference on Industrial Hygiene held in Melbourne in May, 1927, the following resolution was adopted:

(a) Lead paint should not be used in interior painting. The use of lead paints in spray-painting under any circumstances must be regarded as dangerous, and the use of non-lead paints should always receive consideration.

(b) Commercial spray-painting in interiors should be done in properly constructed booths, provided with efficient mechanical exhaust ventilation. The exhaust systems should be so constructed and installed as to operate effectively, independent of weather and adjacent building conditions.

(c) The booths act as extraction-dust ventilating units, and the spray operator should not be exposed to dust and fumes drawn past him to the exhaust fan.

(d) The exhaust system should produce a satisfactory uniform air movement at the booth face under working conditions.

It is recommended also that employes engaged in spray-painting should—

(a) Not spray at right angles to a flat surface, so causing the spray to roll back

(b) Not spray too large objects and thus get out of range of the exhaust

(c) Not spray promiscuously about the room in testing the sprayer

In the matter of safeguards regarding volatile solvents, etc., the special committee recommended that paints, etc., containing benzol should not be used nor should benzol as such be added to any paint material. Where penetrating stains and removers containing benzol

are used, as many men as practicable should be employed to minimize the period of exposure to the injurious effects of benzol. Shellac dissolved in wood alcohol should not be used, nor should wood alcohol as such be used in any painting operation. Dr. J. I. Moore, Commissioner of Public Health for Queensland, *Med. Off.*, Jan. 21, 1928, p. 33.

The Determination of Carbon Monoxide in Mines With the "Iodine Pentoxide" Detector—The various methods commonly used by the Bureau of Mines for detecting carbon monoxide include the use of canary birds and mice, the pyrotannic acid method in blood samples, volumetric gas analysis, and the iodine pentoxide method. This is also known as the hoolamite method. (The article contains a description of the detector which is composed of a short barrel about 1 inch in diameter and 6 inches long to which is attached a rubber bulb, a tube containing the hoolamite and the indicator tube.) By using more samples of the air, amounts as low as 0.05 per cent can be estimated. While the hoolamite detector does not indicate a deficiency of oxygen or the presence of other gases as carbon dioxide and hydrogen sulphide, nor give warning of the presence of carbon monoxide unless it is actually used (differing from a canary), it affords a reasonably accurate quantitative means of determining, while underground, the percentage of carbon monoxide in the air, which it is impossible to do with small animals. It is an extremely valuable tool in mine rescue work.—G. S. McCaa and John A. Davis, *Circular No. 6057*, U. S. Bur. of Mines, Jan., 1928..

Anthrax Hazard in Pennsylvania—In view of the recent report of several fatal cases in one plant in Philadelphia in recent weeks, it is well to call attention to the carefully detailed study of

14 fatal and 75 non-fatal cases of anthrax which have occurred in Pennsylvania during the 5 years ending 1926, by Dr. Elizabeth B. Bricker, Department of Labor and Industry, Pennsylvania, *Month. Labor Rev.*, 25, 6:1261, (Dec.), 1927.

Prevention of Hydrogen Sulphide Poisoning in Handling and Refining High-Sulphur Petroleum—Several fatal accidents have occurred in the oil fields and at refineries from hydrogen sulphide poisoning. The general characteristics of this gas show that it is heavier than air, is colorless, and has a characteristic odor known as "rotten." It burns in air with a blue flame yielding sulphur dioxide and water vapor. It is therefore an "acid" gas. It becomes less soluble in water as the temperature is raised from the freezing point. It is a highly corrosive agent, leads to blackening of white lead paint, and is extremely toxic, in this respect more so than hydrocyanic acid gas. In high concentration it quickly deadens the sense of smell and the margin between consciousness and unconsciousness and death is very narrow. "Probably one breath of the gas may be sufficient to cause asphyxiation." Exposure to low concentrations causes irritation of the eyes and of the respiratory tract. (The paper next discusses the treatment of victims, the places of danger in the oil refining industry, descriptions of typical cases of poisoning, and the details of precautions necessary in the care of apparatus, tanks, etc. An appendix gives a satisfactory method for the determination of hydrogen sulphide by titrating with iodine solution.)—H. C. Fowler, *Serial No. 2847*, U. S. Bur. of Mines, Dec., 1927, 27 pp.

Ozone Fallacy in Garage Ventilation—Dr. Salls presents a discussion of the literature concerned with the reaction of carbon monoxide and ozone, and

from this discussion one must conclude that there is great variance in the literature concerned with this reaction.

The experimental studies which Dr. Salls presents are analyses of the atmosphere from a gassing chamber in which carbon monoxide is mixed with ozone at room temperature. The atmosphere was sampled from the beginning of the mixture of the gases to a period 140 minutes thereafter. The carbon monoxide determinations were made by means of the Sayers-Yant method, using defibrinated steer's blood as a blood reagent. Three samples of the atmosphere were obtained prior to starting the ozonator, the three samples yielding the following results in chronological order: 13, 9 and 7 parts of carbon monoxide. After allowing the ozonator to operate for about 20 minutes, a sample was taken which yielded somewhat less than 5 parts of carbon monoxide. Subsequent samples were taken to the end of 140 minutes. When these samples were plotted against time they fell on a fairly uniform curve which appears to be the curve of absorption of gas by the chamber walls and leakage through them. The starting of the ozonator appears to have altered the shape of the curve in no way.

Dr. Salls concludes that this study indicated no evidence of an appreciable action of the ozone on the carbon monoxide.—Carroll M. Salls, *J. Indust. Hyg.*, IX. 12:503. (Dec.), 1927. L. G.

Review of Literature on the Physiologic Effects of Abnormal Temperatures and Humidities—Among the rather lengthy conclusions reached in this study we note the following:

The upper limit in atmospheric conditions at which work can be performed efficiently corresponds to a dry-bulb temperature of 100° and a relative humidity of 30 per cent, or 90° to 95° F. in still saturated air, even when stripped to the waist. The optimum temperature at rest is around 66° F.; and with hard work the optimum temperature is 59.5°; 43° F.

was pronounced as too cold with or without air movement, regardless of humidity. In still air no temperature is too low to prevent outdoor work.

The lowest temperature compatible with life is said to be 78.8° F., although LeFèvre found that a rabbit died when the temperature of the rectum had fallen to between 60° and 65° F.

The minimum accident frequency, according to one observer, in factory work in both men and women was at 65° and 69° F. . . . At temperatures above 69° the accident frequency showed only a slight rise in women, but in men it increased rapidly, and at temperatures above 75° it was 39 per cent greater.

During the 16 months preceding the installation of the cooling plant in the Morro Velho mine there were 20 fatal accidents, while during the 16 months period following the installation there were only 6 fatal accidents.

(Many other interesting conclusions are found in this report.)—R. R. Sayers and S. J. Davenport, *Pub. Health Rep.*, 42:933, 1927.

Degree of Nicotine Action on Workman's Organism From Inhaled Tobacco Dust—This study was designed to answer the following specific questions with reference to the problem of nicotine action on workman's organism: (1) the quantity of tobacco dust inhaled by a workman; (2) how the inhaled dust is distributed in the body; (3) how much nicotine is present in the dust; and (4) what amount of the nicotine is alkalized by the different juices of the human body.

The method of making dust estimations is not given but the author pre-

sents data showing that from 2.8 to 17.3 milligrams of dust were inhaled by workmen during one hour. Of this amount a portion was obviously exhaled, a certain portion retained in the nose, and a certain portion, from approximately 9 to 55 mg., penetrates into the lungs during a period of 24 hours of exposure.

In attempts to estimate the degree of nicotine alkalization by different body juices, the author has experimented with saliva, gastric juice, physiological saline and intestinal juice to which pancreatic juice or bile, or both, were added. From these experiments the author concludes that the total nicotine intake from inhaled tobacco dust during an 8-hour workday ranges from 0.3 to 1.9 mg., depending on the process at which the worker is engaged. He concludes that the workman employed at rubbing tobacco, the dustiest process, absorbs as much nicotine from the dust as he would by smoking 5 cigarettes a day. This small amount of nicotine certainly does not explain the cases of nicotine poisoning which have been observed, and the author is of the opinion that the atmosphere of tobacco factories contains volatilized nicotine in free condition which is more capable of producing action than is inhaled dust. The average nicotine content of tobacco dust on the basis of several analyses performed by the author proved to be 1.73 per cent.—A. Burstein, *J. Indust. Hyg.*, IX. 12:512. (Dec.), 1927. L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

Blood Regeneration in Severe Anemia—X. Assimilation and Conservation of Bile Pigment, Blood Hemoglobin and Muscle Hemoglobin—Hemoglobin prepared from normal dog blood in isotonic saline solution was injected hypodermically into anemic dogs, both intravenously and intraperitoneally. Muscle hemoglobin free from blood hemoglobin was also tried, as was a pancreatic digestion of red blood cells of the dog administered in an alkaline medium. The intravenous injection of dog hemoglobin in varying amounts resulted in all instances in a conservation of the injected hemoglobin amounting probably to 90 per cent or more. While muscle hemoglobin is utilized to form new hemoglobin it is not so satisfactory, as the dog can tolerate only small amounts of this substance compared with blood hemoglobin. Muscle hemoglobin solution is apparently toxic when fed in large amounts. A pancreatic digestion of red blood cells resulted in a regeneration of about 40 per cent and in the case of fresh blood cells given by mouth there resulted only a 7 to 10 per cent utilization, probably due to incomplete digestion of hemoglobin. Dried blood cells in the form of blood paste were fed with a 20 per cent utilization as a result. A number of experiments in bile feeding with dried ox and pig bile gave negative results. Fresh dog bile given by stomach tube or mixed with the standard ration showed some stimulus to hemoglobin production but in some cases results were negative. A discussion follows as to the probable site of the conservation of hemoglobin in the body.

XI. Iron Effect Separated from Organ

Effect in Diet—Experiments are recorded in which soluble iron salts corresponding to the iron content of about 300 grams of fresh spleen were added to the standard ration. These small doses resulted in production of an excess of 10-25 g. of hemoglobin, for 2-week periods, above control levels. Two hundred to 300 g. cooked spleen caused an increase of 20-50 g. in the same period. It was found, however, that dogs on a diet of iron salts may or may not respond with increased hemoglobin production depending on the condition of iron shortage. The addition of pig kidney and liver showed a marked increase. It is concluded that this summation of physiological effect of iron salts plus organs does not support the contention that the favorable influence of the feeding of these organs toward hemoglobin regeneration is due to the iron content.—F. S. Robscheit-Robbins and G. H. Whipple, *Am. J. Physiol.*, 83:60-83 (Dec.), 1927.

Studies on the Anemia of Rice Disease—On the theory that bacteremia in this disease is the result of gastrointestinal stasis, the effect of four procedures were studied—first, increasing the acidity of digestive juices; second, through the addition of vitamins A and C to correct deficiency; third, to alter the character of the intestinal flora by increasing acidophilic bacteria; fourth, altering the degree of absorption from the gastrointestinal tract by administering lactose, magnesium sulphate or mineral oil. Adult pigeons, averaging 360 g. in weight, were the experimental animals. The birds were placed on a mixed whole grain diet and after con-

stant weight had been established, records were made of body weight, respiration rate, rectal temperature, red corpuscle count, hemoglobin and blood sugar levels. The addition to the diet of betaine HCl, lactose, vitamins A and C, magnesium sulphate or mineral oil had no apparent influence on body weights, temperature and respiration. Betaine HCl or butter and orange juice in addition to the rice diet had no influence on the red corpuscle count. The addition of lactose, magnesium sulphate or mineral oil prevented anemia in a large percentage of cases. Magnesium sulphate, mineral oil or lactose did not change the blood sugar concentration. It is concluded that the beneficial effects observed in rice disease, so far as the red blood cell count and hemoglobin levels are concerned, following the administration of mineral oil or magnesium sulphate and lactose, is explained by the catharsis and limitation of intestinal bacteremia.—O. W. Barlow, *Am. J. Physiol.*, 83:237 (Dec.), 1927.

Food Poisoning—This is an epidemiologic study of 425 outbreaks of food poisoning in the United States during 1923, 1924 and 1925. It is admitted that accurate statistics are difficult to obtain on account of the fact that food poisoning is rarely required to be reported, although such reports are required in the States of Georgia, Kansas, Maryland, Montana, New Mexico, Oklahoma, Washington, Wyoming and West Virginia. Botulism is a reportable disease in Colorado, Connecticut, Arizona, Idaho, Kansas, Maryland, New York, Minnesota, Oregon, Washington, California, West Virginia and Wyoming. A summary of the data available for the period 1910-1925 inclusive, shows 7,112 cases with 544 deaths, indicating a case mortality of 7.6 per cent. It was concluded that this figure does not accurately represent the mortality owing to analyses of necropsies in assigning

the cause of death. A careful study of the records, selecting those cases in which laboratory evidence was reasonably conclusive that the cause of the outbreak was the paratyphoid group, shows a case mortality of 0.4 per cent. Four hundred and twenty-five investigations of alleged food poisoning are summarized for 1923-24 and 1925. The outbreaks bear no relation to the time of the year. Geographically, the greatest number were reported in the middle west, followed by the southern group, the western group and the smallest number in the east. Of the foods alleged responsible, 401 were commercially canned and 70 prepared in the home. The type of food involved was chiefly meat products, fish, vegetables and fruit. It was apparent that neither age nor sex has any incidental influence on the distribution of outbreaks. Of 425 outbreaks, in 28 the food was regarded as manifestly spoiled or off in taste or odor. Of these, 23 were outbreaks of botulism. Eight cases of botulism are recorded in which the food was stated to be normal in odor and taste. Sixty-six cases out of 425 recorded are classified as being caused by the paratyphoid-enteritis group of organisms, although the majority are not supported by laboratory evidence. In 32 per cent of the series reported, the diagnoses were given by attending physicians as "ptomaine poisoning." The same term was also used by newspaper reporters and others. It is insisted that this loose term should be promptly discarded by the medical profession and that the diagnosis of food poisoning should be supported by epidemiologic, bacteriologic and toxicologic investigation.—*J. A. M. A.*, 90: 459 (Feb. 11), 1928.

Vitamins A, B and C in Collards and Turnip Greens—In determining vitamin B, normal albino rats, 28 days old, and of uniform weight as nearly as possible, were used. All animals were

kept under the same conditions of light and heat, and were fed at a nearly uniform hour seven days a week for 8 weeks. The diet was devoid of vitamin B and distilled water was given *ad libitum*. It was found that 0.8 g. raw turnip greens and 0.9 g. raw collards were sufficient for maintenance over a period of 8 weeks. Cooking according to the process described caused a 10 per cent destruction of vitamin B in turnip greens and 40-45 per cent in collards. In determining vitamin A, rats 28 days old, weighing 40-55 g. were used; 0.02 g. raw turnip greens was more than sufficient to produce growth of 25 g. in 8 weeks, and 0.02-0.04 g. collards was sufficient to give standard growth. Cooking showed no appreciable destruction of vitamin A. In determining vitamin C, guinea pigs were used. The experimental diet consisted of 59 per cent whole ground oats, 10 per cent butter fat, 1 per cent sodium chloride, and 30 per cent skim milk powder. It was found that 0.5 g. of raw collards and more than 1.0 g. of raw turnip greens were required to prevent scurvy. Cooked collards, equivalent to 10 g. raw, gave protection, while cooked turnip greens, equivalent to 8 g. raw, were not sufficient and the animals refused to eat more. Tables are given in each instance showing the growth and survival of rats during the 8-week period.—G. W. Burton, *J. Home Econ.*, 20:35 (Jan.), 1928.

A Milk-Borne Epidemic of Poliomyelitis—In October, 1926, in Broadstairs, England, there occurred an unusually severe outbreak of poliomyelitis which presented features not generally encountered in epidemics of this disease. This outbreak started and subsided suddenly, 62 cases being reported between October 14 and 29. The epidemic was confined strictly to Broadstairs and did not extend to the adjacent cities. These localizing features were rather unusual.

Evidence of flaccid paralysis was obtained in 43 of the cases while 28 cases were classed as non-paralytic, although some of them exhibited encephalitic symptoms. It was observed that the encephalitic type of the disease was much more common in this epidemic than in the experience of the writer in the United States. Investigation disclosed that practically all the cases among the residents of Broadstairs were supplied with milk from the same dealer. The evidence concerning the milk supply pointed strongly to the milk furnished by this dealer as the common source of infection, and further suggests that contamination of only one grade of his milk which came from a single farm, was responsible for the epidemic. The author further concludes that the distribution of cases of poliomyelitis in the Broadstairs epidemic in point of time indicates that the majority of cases were simultaneously infected. It is also inferred that the incubation period in the majority of cases was between 6 and 14 days. The age distribution in this epidemic differs from that usually observed, in that most cases occurred between the ages of 5 and 15. This is largely accounted for by the cases in boarding schools and convalescent homes located in this city whose population consisted largely of children between these ages.—W. Lloyd Aycock, *Am. J. Hyg.*, 7:6 (Nov.), 1927.

Food Poisoning Probably Caused By *Bacillus Proteus*—A report of poisoning among students at Colgate University, Hamilton, N. Y., October 4, 1927, the cause of which appeared to be chicken which had been purchased on Sunday and not used until Tuesday. Fortunately some of the chicken was secured and *B. proteus* found together with streptococci and colon bacilli. Samples from the vomitus and stools of the patients also yielded *B. proteus* which were found to be pathogenic for

guinea pigs. Symptoms are recorded which simulate those caused by the paratyphoid-enteriditis group of organisms.—Dr. Morrill L. Ilsley, *J. A. M. A.*, 90:292 (Jan. 28), 1928.

The Relation of Deficiency of Vitamin B to Atony of the Stomach
—Five rats of known history were placed on a vitamin B deficient diet supplemented with 1 per cent yeast extract for 6 weeks. Barium carbonate meals were then given and radiograms made, which disclose a distension of the cardiac portion of the stomach, in some of the rats so great as to be visible externally.

Control rats on a sufficient vitamin B diet were all radiographed showing no enlargement of the cardiac and the stomachs only about one-third the size of those on the deficient diet. Control rats were of the same weight as the deficient rats when the radiograms were taken. The authors conclude that the atonic conditions among some patients may be the result of vitamin B deficiency.—Dr. M. J. Rowlands and Dr. Ethel Browning, *Lancet*, 1:180 (Jan. 28), 1928.

The Possible Toxicity of Buttermilk Soured in Zinc Containers—The investigators first confirmed the previously reported presence of zinc in fresh milk and cultured buttermilk and further found that cultured buttermilk dissolves considerable quantities of zinc in galvanized containers which amounts depend on the acidity of the milk and the time factor. Rats and swine were used as experimental animals, the former after being placed on the experimental diet were given buttermilk soured in glass and in both old and new galvanized utensils. Measured amounts of zinc lactate and zinc carbonate were

also administered in two lots. The lot fed 0.5 per cent of zinc lactate made fair growth and reproduced but a large proportion of the off-spring died, while the lot fed 1 per cent of the zinc carbonate made poor growth and did not reproduce. For tests with swine, 100 pound Hampshire gilts were the experimental animals, divided into 4 lots, one being fed 0.5 per cent of zinc carbonate, another plain buttermilk, a third buttermilk from a galvanized tank, and the fourth, cultured buttermilk held from 12 to 48 hours in new galvanized iron pails. In lot 1, after feeding zinc carbonate for 2 weeks, one animal developed stiffness of the hind legs but the mate was unaffected. Apparently no deleterious effects were observed in the case of sows which were fed buttermilk stored in galvanized tanks or pails. The authors conclude that small amounts of zinc lactate such as might be found in food does not markedly affect growth and reproduction in rats.—A. D. Burke and Frank Woodson, *J. Dairy Sci.*, 11: 79 (Jan.), 1928.

Determination of Vitamin A Content in Liver Oil of the Dog-Fish *Squalus Sucklii* (preliminary note)—The content of vitamin A in the freshly prepared liver oil of the dogfish (*S. sucklii*) was compared with that of a standard cod liver oil stated to contain 12,000 units of vitamin A per ounce, using curative and prophylactic tests with rats on the Zilva-Miura basal diet. Comparisons of the weight increases of rats given cod liver oil and the dogfish liver oil indicate that for equal volumes the dogfish liver oil contains between 5 and 10 times the number of units present in the cod liver oil.—H. N. Brocklesby, *Canad. Chem. & Metall.*, 11 (1927), 9:238, 239, figs. 2. Abstract. *Exper. Sta. Rec.*, 58:294 (Feb.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

The Mother-Fed Baby—Dr. Waller's address given to the Winter School for Health Visitors contains so many excellent points which are often insufficiently emphasized that it seems worth while to review them.

In many bottle-fed babies early loss of muscle tone becomes an important warning of faulty nutrition and particularly of oncoming rickets. Dr. Waller does not, however, feel that mother's milk is an infallible protection against rickets and urges that the effective diet and way of living on the antirachitic vitamin of mother's milk be borne in mind. It is quite possible this may account for the steady gain of some breast-fed babies whose mothers may not keep as neat homes as more conscientious mothers, but who do get out of doors daily into the sun and fresh air.

Immunity against the so-called children's diseases is not always certain in the breast-fed. Measles is rarely contracted before the seventh or eighth month. Most nursing mothers in this group had had measles, but so had the mothers of bottle-fed infants, and the most that could be claimed was that the incidence of measles was somewhat delayed in the breast-fed infants. Pertussis, however, is common any time after the first month of life, nor did breast milk appear to protect from this or from diphtheria and smallpox, although recent vaccination of the mother appears to lessen the chance of the baby's contracting smallpox. In cases of congenital syphilis Dr. Waller feels strongly that both the breast-fed baby and mother should be treated and not the mother alone. He agrees, of course, that the tuberculous mother should not nurse her baby. Breast milk not only

helps to combat disease when it occurs, but it is the only perfect food during the baby's illness and convalescence.

The close mental—and physical bond between the nursing mother and her baby was especially well brought out. While firmly supporting the principle of punctual feeding Dr. Waller feels that the strict separation of the mother from her baby during the lying-in period is "bad natural history." The mother "should be allowed to handle her baby and cultivate and indulge her maternal feelings."

Certain gastrointestinal disturbances occur in breast-fed children following such things as worry, quarrels, shocks, which affect the mother. A feed shortly after some such disturbance frequently provokes vomiting in the child, and sometimes this occurs with the return of the menses for 2 or 3 three days, but this is not to be taken as sufficient reason for stopping breast feeding. The breast-fed baby frequently runs a risk of catching its mother's cold, and this, in the neonatal period, is a serious occurrence. The mothers should be assiduously taught to mask themselves when feeding their infants. Colds, however, are generally less severe in the breast-fed than in the bottle-fed baby.—

Dr. H. K. Waller, *Maternity and Child Welfare*, Feb., 1928.

Rheumatic Infection in Childhood—Rheumatic infection in children is doubly serious in that it entirely disables them during the attack and also tends to produce permanent cardiac injury. This report from the Ministry of Health, England, is a study of the bacteriology, incidence and institutional treatment of acute rheumatism in children in connection with the prevention of heart disease.

Diseases of the heart and circulation account for 188 of every thousand

deaths. Of these 40 per cent are probably due to rheumatic infection. If we turn to the number of patients in hospitals with cardiac disease we find the cause is definitely acute rheumatism in 90 per cent of the cases under 10 years of age, 80 per cent between 10 and 20 years, 60-70 per cent between 20 and 40 years, so that nearly all cardiac deaths under 40 are due to "rheumatic infection." The poorer the home the greater the risk of infection; also the younger the children having rheumatic infection the more likelihood of cardiac involvement.

Rest being a great factor in the prevention of permanent heart damage following infection, institutional treatment seems to be indispensable. Treatment in the child's home or at the ordinary convalescent home is rarely successful. It is best done in institutions devoted entirely to cardiac patients. Complete rest in bed can, however, be over-prolonged. The standards now used in the institutions mentioned are complete rest until 3 weeks after, (1) the pulse-rate and temperature have become normal; (2) anaemia has disappeared; (3) the heart signs are unchanged. It should always be borne in mind that one attack renders the child more liable to another and every precaution should be taken to prevent recurrence.

(This study follows that made by the Ministry of Health, England, in 1924 and dealing with the insured population over the age of sixteen).—*Mat. & Child Welfare, London*, Jan., 1928.

Quantitative Study of Ultra-violet Transmitting Glasses—In view of the importance of the subject, it is highly desirable that as many studies as possible be made of the efficiency of ultra-violet transmitting glasses. The authors in their study used a series of quartz lenses and prisms so arranged as to enable them to select wave lengths or

groups of wave lengths and to make actual quantitative measurements.

The conclusion to which Goodman and Anderson come may be expressed by their final statement, which is as follows:

"In conclusion we would like to point out that a number of excellent window glass substitutes for transmitting the short ultra-violet rays of the sunlight are now available. We have discussed briefly the available data on the ultra-violet of sunlight, referring primarily to its variability in quality and quantity with time of year and weather conditions. We know of no evidence that has been advanced to substantiate claims that health would be improved by using such glass substitutes, and until carefully controlled experiments have demonstrated their value, their employment as an aid to health should be advocated with reservations."—Herman Goodman, M.D., and William T. Anderson, Jr., Ph.D., *Boston M. & S. J.*, Jan. 12, 1928.

Study of Stillbirths Occurring in 4000 Consecutive Deliveries—At the Woman's Hospital 4,000 deliveries were studied in connection with maternal mortality, infant mortality and stillbirths. As Dr. Lyon so aptly states, these 3 points illustrate statistically "efficiency and good treatment in a most impartial way" on any obstetric service.

Among these 4,000 deliveries there were classified as stillbirths those babies who never breathed even though the heart-beat continued after birth and those who were delivered between the 28th week and term. On this basis 105 stillborn babies and 104 mothers (1 case of twins) were gone over in careful detail. Autopsy was performed in 53 cases.

A separate study was also made of 41 cases in which the heart was heard during part or all of labor. An analysis of these 41 cases suggested that 8 babies

might have been saved if a different method of delivery had been used, and 12 others if earlier operative interference had taken place. In the remaining 21 of this particular group the stillbirths seemed unavoidable and a detailed summary of diagnoses is given. This article presents so valuable and comprehensive a survey of one of our most puzzling problems that we venture to quote the remainder of the summary in full. Presumably no maternal death occurred in the group studied as no mention is made of maternal mortality.

SUMMARY

1 There were 104 patients who had 105 stillborn babies, or 26 stillbirths per 1,000 deliveries.

2 There were 85 of these patients who had been attending the prenatal clinic, giving 21 stillbirths, among clinic patients, per 1,000 deliveries.

3 There were 25 patients who showed evidences of toxemia, and 4 of these had convulsions.

4 Nine patients among the 79 who had Wassermanns were 4 plus. One showed clinical evidences of syphilis. To these luetic mothers 2 babies were born with syphilis. No other babies gave any signs of syphilis.

5 There were 61 abnormal deliveries, 22 being by forceps and 39 by breech.

6 There were 90 patients who had normal pelvic measurements.

7 There were 37 premature babies and 44 were macerated.

8 There occurred 11 cases of prolapsed cord in 10 of which it was a contributory or actual cause of stillbirth.

9 There were 53 babies autopsied and 12 of these showed cerebral injury.

10 In 55 patients no fetal heart was heard on admission, and in 3 it was doubtful. The heart in 47 was heard on admission and in 41 of these subsequently during part or all of the labor.—

Edward C. Lyon, Jr., M.D., *Am. J. Obst. & Gynec.* Oct., 1927.

Great Britain's Shortage of Young People—"As an aftermath of the war, Great Britain expects within the next few years a considerable decrease in the proportion of boys and girls 14 to 18 years of age in the general population, with a corresponding decrease, estimated to be about 389,000, in the number seeking juvenile employment. This circumstance has inspired the authorities to recommend an investigation into all the prospects and conditions of juvenile employment in various areas and trades, an inquiry which will greatly add to the industrial information already in the hands of juvenile-employment committees, and thus at the disposal of parents, children leaving school, and welfare workers."—*World's Children*, Children's Bureau, Dept. of Labor, Feb. 24, 1928.

Hospital for Crippled Children, University of Chicago

THE Home for Destitute Crippled Children of Chicago is to transfer its main hospital to the campus of the University of Chicago, where new buildings providing 100 beds will be erected. Part of the present plant of the home will be maintained as an emergency hospital and free dispensary for the west side. The

hospital will remain under the jurisdiction of the institution, but the university will provide the medical care. This is the fifth hospital for children's work now connected with the university, and its addition means another step toward establishing a clinic similar to those in Vienna and Berlin.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Tioga County Ends Demonstration Period—The Tioga County Maternity Nursing Service developed under the joint direction of the New York State Department of Health and the Maternity Center Association in 1925 has as its object: "The working out of practical methods and standards of maternity hygiene work in rural communities using as a basis the methods and standards employed by the Maternity Center Association in New York City." This work was part of the Sheppard-Towner program.

In the beginning, it was agreed that "no prenatal medical clinic will be started unless there seems to be a special need, but patients will be brought into contact with the local physicians by the nurses and we will try to have the work, ordinarily done at a clinic, done by the doctors for each individual patient." It was agreed to begin with Maternity Center technics and to make changes as they were indicated. There was only one change made: fewer postpartum visits were necessary to secure the same results.

December 31, 1927, closed the 2-year period of the demonstration. The work of the nurses has become generalized * and the County has appropriated sufficient money which, with the money received from the State County grant, will finance this county nursing service.

At the end of the first year, 72 per cent of the pregnant women in the county were receiving nursing care and 75 per cent of this group had been reported by the private physicians. The second year, 356 patients received care and more than one-half of them were reported by physicians. The majority

of the balance made personal application for the service. (There are approximately 375 births a year.)

The private doctors in Tioga County did everything possible to facilitate the development of this service. H. C.

* This experience emphasizes again that no adequate maternity service can be carried on without the development of a general service. Only when we consider everything that may affect the health, happiness and peace of mind of the pregnant mother do we give adequate care.

A Campaign Against Rickets—A study of the vital statistics of the Mulberry Health Center district in New York City showed an unusually high death rate for infants from 6 months to 1 year with one-third of the deaths from pneumonia. It is believed that rickets causes a susceptibility to colds, bronchitis and pneumonia and, since rickets is almost universal among infants, it is hoped by reducing the prevalence of rickets the high infant sickness and death rate can also be reduced.

For this reason a campaign against rickets with the coöperation of physicians, midwives, health agencies, druggists, cod liver oil companies and prominent citizens has been launched by Mulberry Health Center, a branch of the New York Association for Improving the Condition of the Poor.

Talks illustrated by charts, slides and films are given to Mothers' Clubs, Parent Teacher Associations, etc., to stimulate interest in sunning babies during all months when this is possible and in giving potent cod liver oil regularly as a supplementary treatment.

Classes have been formed to teach mothers the harmfulness and the prevention of rickets. These classes reach

pregnant women and mothers of babies under 2 years. Classes for older girls receive instruction in infant care, including the importance of sunshine and "bottled sunshine."

The hope of Mulberry Health Center is to broadcast the knowledge of rickets and the saving properties of sunshine and cod liver oil through posters displayed in shop windows, libraries, banks, health and welfare organizations; through flyers which are left in every home; through a pamphlet, *Rickets Must Go*, which has been distributed to the educators in the district. This material used is available to other agencies. Information may be had by writing to Mulberry Health Center, 256 Mott Street, New York, N. Y. C. R. P.

Community Health Resources Studied—Surveys of one kind or another, dealing with either self-analysis or group analysis, are growing in popularity. In weighing the pros and cons of health services, these investigations are especially useful. A study of community health resources is being undertaken on a state-wide basis by the Department of Public Welfare under the auspices of the General Federation of Women's Clubs, and endorsed by the American Public Health Association. This organized effort on the part of so large a body of women, enlisted in behalf of public health projects, will, without a doubt, result in direct benefit to many communities.

The study is in the nature of a contest, and the award will be made to the state having the greatest proportion of Women's Clubs making studies. The award, which will be contributed by the American Public Health Association and the American Child Health Association, will be made at the close of the contest, March 31, 1928, in a form to be worked out in consultation with the official health agencies and the authorities of state and federal departments of health

—a wise provision designed to meet the immediate need of the particular state in question.—Suggested Outline for the Use of Women's Clubs in the Study of Local Nursing Services, *Pub. Health Nurse*, XIX, 12:620 (Dec.), 1927.

Cleveland's Study of the Needs of Chronic Patients—The facts brought out in the survey made by Cleveland of their problem of chronic patients may be helpful to other communities that are aware of the imperfections of the care which they are providing for this group. Howard Whipple Green, Secretary of the Cleveland Health Council, has given a brief analysis of this study in the November issue of *The Nation's Health*.

The 460 cases studied were patients either in hospitals or at the City Infirmary, or known to the nursing associations and family case working groups in June, 1927. They were chosen according to the definition of a chronic given by Dr. Ernest Boas as "one who requires hospital care for a period from 3 months to several years."

Of these 460, 26 per cent were in need of medical study for diagnosis and treatment; 52 per cent in need of nursing care only, and 22 per cent in need of custodial care only. Three hundred and ninety-eight of the 460 patients were classified as indigent, and 410 of them eligible for care in a city chronic hospital. At the present time a large number are occupying beds in hospitals for the acute which should be available for the acutely ill, and which are much more expensive to maintain than beds in adequate hospitals for chronics would be. A large number are also being cared for in the much overcrowded City Infirmary.

The age groups show 27 per cent under 40, and 60 per cent under 60 years of age, and of these a certain number could probably be returned to their homes and to work after proper

diagnosis and treatment, which would be available in a chronic hospital. There are many who are receiving inadequate care at home and would benefit by care in a chronic hospital. In other instances removal of the chronic patients from the home would release members of the household who need to work to contribute to the support of the family.

On the whole, there seemed to be clear indication of the need for a city hospital in Cleveland exclusively for chronic patients.

These findings will be of interest as useful preliminary material on a subject which is to receive much attention and study throughout the country in the near future.—An Analysis and Classification of Cleveland Chronics, *Nation's Health*, IX, 11 (Nov.), 1927.

K. E. P.

Tuberculosis in Children—A sound and concrete article on "Tuberculosis in Children" by Dr. J. A. Myers, Director of the Lymanhurst School in Minneapolis, appears in the December issue of the *American Journal of Nursing*. The clear-cut discussion of diagnosis, treatment, and prevention should appeal to every public health nurse, whether or not she is doing specialized tuberculosis nursing.

Diagnosis in children requires great patience and understanding, says Dr. Myers. It begins with:

History—of previous illnesses, of the nature and quality of the child's food, of his physical activities and attitude toward play, and of his growth.

Examination is the next step. This includes: The tuberculin test, which must be understandingly interpreted; microscopic examination of discharges; physical examination, with emphasis on the lymph nodes and joints, and X-ray of chest and other suspected parts.

Treatment in childhood is more hopeful than at any other period in life, perhaps because tuberculosis in children is

apt to be a disease of the lymph nodes, which are in themselves protective mechanisms.

Conservation of energy is one of the first requisites in treatment. The child should be under medical and nursing supervision, that activities may be carefully regulated. Food of the right kind and amount is essential; a good deal of food is usually advisable. Good ventilation—air baths and heliotherapy—are also important factors in treatment.

Prevention is, of course, all-important. Unreported cases must be watched for. Known cases must learn how to protect others and be led to accept responsibility for doing so. Food must be uncontaminated; milk should be pasteurized. Children should be taught personal hygiene, and thoroughly understand how to keep themselves efficient and strong.

In conjunction with this discussion, it is interesting to refer to the article on Standards for Tuberculosis Work in a Generalized Nursing Program, an outline of East Harlem findings, published in *The Public Health Nurse* of November, 1926 (XVIII, 11:578).—J. A. Myers, M. D., Tuberculosis in Children, *Am. J. Nurs.*, XXVII, 12:1038 (Dec.), 1927.

L. A. D.

The Public Health Nurse in the Control of Communicable Diseases

—The public health nurse holds a strategic position in the prevention of communicable disease. Her access to homes gives her an opportunity of discovering sources of information which might not otherwise be known. Although she is not able to make diagnoses, she should refer to the health officer at once persons whom she considers suspicious of having reportable diseases. As different communities may have slightly different procedures and beliefs in regard to the use of vaccines and sera, exclusion from school, quarantine, etc., it is necessary that she be

advised by the local health officer as to the practices in her community.

Some diseases are entirely preventable, such as diphtheria, smallpox, and typhoid. The attention of research workers is directed to others in the hope of also finding the means of completely controlling these. As example is the best teacher, the nurse should be protected from diseases where protection is available. Dr. Sayer also advises that she be Dick tested and immunized if found to be susceptible to scarlet fever.

Toxin-antitoxin and antitoxin are the weapons against diphtheria, each powerful in its place; antitoxin to give relief where cases exist or to protect exposed persons from the disease; toxin-antitoxin when there is time enough to allow protection to develop. All children who have received toxin-antitoxin may not be immune and, therefore, it is necessary to have the Schick test given to make sure protection is established.

Vaccination against smallpox will give absolute protection for several years. Where cases of the disease exist, the nurse can be of use in helping to trace all possible contacts and checking up on their vaccination.

The best defense against typhoid is immunization by means of typhoid vaccine. Persons who have had typhoid should also be watched to determine carriers and to make sure that no carrier is a food handler.

As the use of serum in the treatment of scarlet fever is still unstandardized, the nurse should know how the health officer regards the use of this. The scarlet fever serum may be compared to

antitoxin as the means of lessening the severity of scarlet fever (but not the length of the quarantine period). The Dick test is comparable to the Schick test. In scarlet fever, toxin is useful in epidemics as immunization develops rapidly. Immunization may cause severe local and general reactions.

Doctors vary widely in their opinions regarding the use of vaccine as a treatment or as a prophylactic in cases of whooping cough. Here, again, the nurse must be wary in advising the use of vaccine and should be guided by the opinion of the health officer.

In cases of measles, it is the special work of the nurse to prevent the disease among infants and small children, the group in which the mortality is greatest. The doctor or health officer is the only one who should suggest the use of convalescent serum.

Nurses may frequently be asked what should be done in cases of dog bite. The wound should always be cauterized by fuming nitric acid. Anti-rabic serum can be given by the attending physician. The head of the dog should be sent to the state laboratory for examination or the dog kept under restraint.—Stanley Sayer, M. D., *Pub. Health Nurse*, XX, 1:4 (Jan.), 1928. B. J. B.

Department of Nursing, Medical College of Virginia—To the graduate nurses of Virginia belongs the credit of presenting a foundation for the Chair of Nursing to the Medical College of Virginia in Richmond, which will be known as the Sadie Heath Cabaniss Department of Nursing.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

Equipping a Campaign—A picture of extensive and varied equipment required for a successful publicity campaign is provided in the catalogue of the 1928 Christmas Seal Sale supplies now being distributed by the National Tuberculosis Association. In addition to campaign manuals and press material the following are offered: posters (11 by 14, 3 styles; 19 by 26; 24 sheet); shop early cards; easel cutouts; poster snipes (2½ by 19; 3 by 28); letterheads; team workers' envelopes; booth envelopes; envelope stuffers (3 styles); follow-up cards; prospect cards (3 styles); personal solicitation cards; lantern slides (2 styles); motion picture trailer (150 feet; 15 feet); stories for children; talking points; self service coin box; bangle pins; buttons (2 styles); head dress; arm bands; electrotypes of Christmas Seals (4 styles); electrotypes for follow-up cards; electrotypes of double-barred cross; electrotypes of envelope stuffer.

When Is a Report a Report?—That an annual report is merely a historical document when it appears six months after the year ends is the contention of C. E. Ridley, National Institute of Public Administration. Under the heading "Promptness" in a study of 12 "typical current municipal reports" Mr. Ridley says: "Only two of the twelve reports were available for distribution within six weeks of the end of the period covered. Five of the twelve reports were not available until six months or more had elapsed. In this rating no credit

whatever is given for a report six months or more late, for it is contended that by that time it has lost all of its news value and therefore its usefulness depends alone upon whatever function it may serve as a means of recording financial statistics and historical events—purposes hardly justified in a report to the taxpayers on the current operation of their municipal government." The 20 points for judging the reports include: Promptness, Size, Important facts, Attractiveness, Diagrams and Charts, Table of Contents, Organization Chart, Recommendations and Accomplishment, Comparative Data, Propaganda. "Propaganda" would better be "Personal Publicity" (photographs of officials, etc.) for the entire report is "propaganda."—Appraising Public Reports. *National Municipal Review*, 261 Broadway, New York, N. Y. March, 1928. 50 cents.

Diphtheria Dramatized—"Delivered with a rush to the speakers' table by a bellhop this telegram introduced a special session of our Conference of State and Local Committees on Tuberculosis and Public Health, State Charities Aid Association of New York:

A murderer of little children is loose in New York State and we believe this killer is now at the Hotel Roosevelt. Won't your health conference find a way to help us?

The Children of New York State.

"The chairman, after solemnly reading the telegram, asked the audience what was to be done. A voice from the rear of the room declared, 'Let's catch this murderer and hold a court to try him.' The suggestion was unanimously accepted by the group, a bailiff and a sheriff were appointed, the door at the rear of the room opened at once and a

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

judge in black robes entered followed by the sheriff who dragged a figure garbed in black with a red mask who was labeled 'Black Diph.' The bailiff called the court to order in a loud voice, ordering all to stand and take off their hats. The judge proceeded solemnly to the bench, rapped for order and the 'trial' began.

"This unique introduction opened the special session on diphtheria prevention. The murderer was accused of slaying 264 children during 1927 in New York State, outside of New York City, and of maiming nearly 4,000 others. The prosecuting attorney was out for blood and called on a series of imposing witnesses to convict the murderer before the Court.

"These witnesses brought out the essential facts about the nature of diphtheria, its prevalence in the state, the principal points about diphtheria prevention campaigns, all conducted in regular Court procedure, with variations. It served to catch the attention of the group and to hold it for over an hour. The Judge in his charge to the Jury summed up the evidence and recommended a verdict banishing the murderer from the state.

"The stunt worked so well at this meeting and required so few properties and time to work it up, that it appears to be well adapted for use locally not only to call attention to diphtheria but to tuberculosis. It could be used to advantage in the organization meeting for a diphtheria prevention campaign, or early diagnosis project.

"What do you think of it?"—Robert W. Osborn, S.C.A.A.

A State Diphtheria Poster Contest
—A poster contest for students in the recognized school art departments in New York outside of New York City is being conducted by the State Department of Education in collaboration with the New York group of state agencies combating diphtheria, and with the coöperation of the National Poster Art

Alliance. The highest prize will be an art scholarship amounting to \$365. The contest runs from February 15 to May 15. The plan as a whole offers practical suggestions for contests in other states. The statement of the diphtheria problem addressed to the students is well done, and the suggestions to the students with the contest rules could be adapted elsewhere. For copies address Marie F. Kirwin, State Committee on Tuberculosis and Public Health, S. C. A. A., 105 East 22d Street, New York, N. Y.

Using Words That Other Folks Use—A staff worker was recently making school inspection in a small town which she had visited some months previously. She asked of a small person undergoing inspection, "And how is your sister?" "Oh she's pretty well, but she has tuberculosis."

"She has tuberculosis?" Why when did you learn that?"

"You said so!"

The records were looked up. The inspector breathed a sigh of understanding when she discovered that the girl had been sent home because of pediculosis, or what ordinary folk call lice.—Reported in *Michigan Out-of-Doors*, Lansing, Mich.

Do We Know? Or Do We Think We Know?—What does the "average" man do in a museum or in an exhibition?—

He wanders aimlessly, yes, but not blindly. His attention is drawn to this and distracted from that. He must have glimmering interests which might be fanned into overt enjoyment. Yet, this casual visitor is in the main a mystery and, if he is to be dealt with effectively, there needs be added to the talking about him and thinking about him deliberate observation of his behavior.

That deliberate observation of his public can be of service to the museum administrator (or the organizer of exhibits—Editor) should not be a novel idea. If there is any single predominant achievement of the psychology of the past quarter-century it lies in the revelation that so far as human nature is concerned acquaintance with is often a far cry from

knowledge about. . . . Most of us felt quite well acquainted with American intelligence before the scientific scrutiny of that capacity in the white draft. And we were acquainted with that intelligence—we were even able to get on with it moderately well—but the deliberate inventory taken by the testers revealed unsuspected facts. Similarly in the present case, there is no reason to believe that the museum director is not acquainted with the casual visitors who wanders through his precincts. Yet, only a few bardy souls would claim that deliberate observation can add nothing to what has been learned informally and passively.

. . . . At the time our studies of the museum visitor were beginning, the Associated Press quietly announced what was under way. Immediately the letter writers and the editorial writers began to volunteer to solve our problems, not by doing our observing for us, but by replacing observation with argument. . . . We wanted to find out as accurately as possible what is actually going on in the museum. And we saw no other way of getting such information than by going after it directly and deliberately.—

In "The Behavior of the Museum Visitor," by Robinson, Sherman and Curry. American Association of Museums, Washington, D. C. 1928. 78 pages. \$.75.

This preliminary report is based on the first two years' work on a study financed by the Carnegie Corporation. It considers museum "fatigue"; the effect of size, position and context upon the individual picture; and guidance by pamphlets. The study suggests application to health exhibitions, and is a reminder of the need of scientific study of human behavior under the impact of various forms of education. Not until such studies are made can we know where we are at in our lavish expenditures of time and money on public health.

"Health Promotion Week"—In Illinois the week is scheduled for two periods: April 1-7 in the 52 counties to the south, and April 22-28 in the 50 northern counties. The week will include the following: Health Sunday, Dental Hygiene Day, Dental Examination Day,

Food Facts Day, Diphtheria Prevention Day, School Health Day, Heart Disease and Cancer Prevention Day.

The "program suggestions" for the series of days are simple, practicable interpretations of the themes as they should be presented by local committees. The concreteness of the topics for the days is a happy contrast to the plan for many health weeks. Unfortunately, this concreteness is partly nullified by the diversity of topics represented in the "educational services and material available" through the state department. Many local committees are likely to distribute printed matter unrelated to the topic of the day. The full program and other material appears in *Illinois Health News*, State Department of Public Health, Springfield. Feb., 1928. *Free*.

Can It Be Instructive?—A state department of health offers in its lists of motion pictures "a one reel combination of four subjects presented in animated cartoon form. It deals with diphtheria, prenatal care, infant feeding and the house fly. Very entertaining and instructive for any type of audience." Probably the "combination" picture is entertaining, but can it be instructive? Can "any type of audience be *instructed* in one session on so many diverse subjects?" Of course, if not too "entertaining" the picture may convince almost "any type of audience" that something or other "will get them if they don't watch out!"

Publicity and Education at Memphis, May 2-9—Five morning sessions and 8 afternoon and dinner sessions, plus several informal luncheon gatherings make up the program of the Committee on Publicity Methods and the Educational Publicity Division of the National Conference of Social Work meeting at Memphis. Among the topics will be: Making Up the Year's Program in Publicity (national, large city, small town), Interviews with secretaries of large

givers on how publicity and appeal letters look to them, Outstanding Publicity Ideas of the Year (including, we hope, some diphtheria and other health features), To Sob or Not to Sob—Trial of the Sob Sister, Letter Clinic, Integrity in Publicity—facts and ethics, The Use of the Welfare Appeal in Commercial Advertising, Where the Publicity Worker Gets His Point of View and Technic, The Use of Demographic Areas in Publicity. Zona Gale will discuss Literary Values in Social Work. For program address Committee on Publicity Methods, 130 East 22d St., New York. Health workers will be welcome. Awards will be made for "unusual achievements in publicity"—newspapers, letters, printed matter. For conditions write the Committee. The exhibits will include much that is new and helpful, and the headquarters will have opportunities for meeting specialists.

COÖPERATING GROUPS

A health program for parent-teacher associations appears in Parent-Teacher Handbook for North Carolina. University of N. C. Press, Chapel Hill, N. C. 50 cents.

The American Junior Red Cross is 10 years old. What it has done and is doing is told in *Red Cross Courier*, Washington, D. C., Oct. 1, 1927. *Free*.

A School Health Appraisal Form, 8 pages, was distributed in September, 1927, by the Iowa State Department of Health to the Parent-Teacher Association of the state. In addition to sending copies of the filled-in form to the State Department of Health, every association was urged to discuss the findings in a November or December meeting.

Condensed information and sources of information about organizations—boys and girls, physical education, etc., are given in Sources of Information on Play and Recreation, by M. P. Williams. Russell Sage Foundation, 130 East 22d

St., New York, N. Y. Revised 1927. \$1.00. With references to material on recreational occupations for camps and institutions.

POPULAR HEALTH ARTICLES

"The Cause of Modern Baldness." *Literary Digest*. Feb. 4, 1928.

"The Dark Arrows of Phoebus," by Frank Thone. *High School Service*, American Red Cross, Feb., 1928. 15 cents. The sun, vitamin D, and rickets.

"Uncle Sam Fitter Than Ever." *Literary Digest*. Feb. 4, 1928. "1927 was the healthiest year."

"Newspaper Recruiting of Students," by Mary Goodyear Earle. *Trained Nurse*, New York. Jan., 1928. One of a series of vocational talks on the professions open to women in the *Herald-Tribune*, New York, N. Y.

EDUCATIONAL MATERIAL

One of the best diphtheria folders I have seen was issued by the Cleveland Health Council, 510 Electric Bldg., Cleveland, O. The most difficult words used are explained thus: "immune (cannot get the disease)" and "sus-cep-table (liable to take the disease)." Good size type and well-printed. Ask for a copy.

Another diphtheria folder rather good in its approach to the reader comes from the Wisconsin State Board of Health. But it has many "hard words," and probably gives more information than is necessary.

Mothers Will Gossip says some "Gossip like this means trouble and sometimes Death!" such as, "Give him something to eat when he cries," etc.; and "Gossip like this means intelligent help that develops fine healthy babies," such as, "My baby was a skeleton until the Health Station taught me about his feeding." Four baby foot-prints, a striking cover design, show before and after care of fallen arches.—Children's Health Service, 578 Madison Ave., New York, N. Y.

LAW AND LEGISLATION

JAMES A. TOBEY, LL.B., DR.P.H.

Traveling Expenses and Income Taxes—Whether members of the American Public Health Association who pay their own expenses in order to attend the Annual Meeting and other professional meetings can deduct these expenses in computing their federal income taxes is now uncertain. In 1922 the U. S. Bureau of Internal Revenue ruled that physicians could not do so, but later the Board of Tax Appeals allowed such a deduction by a chemist who attended a meeting of a national chemical society. The Bureau of Internal Revenue has apparently never given a definite ruling applicable to members of the A. P. H. A., though in a recent letter to the associate editor, the bureau states that such deductions are not allowable.

In order to remedy this unsatisfactory situation, Senator Arthur R. Robinson of Indiana has introduced an amendment to H. R. 1, the Revenue Act of 1928. On page 19 of this measure one of the allowable deductions is for "traveling expenses (including the entire amount expended for meals and lodging) while away from home in the pursuit of a trade or business." Senator Robinson's amendment would add to this section the following: "or in attending meetings of trades or business organizations of which the taxpayer is a member." If this amendment is adopted, there would apparently be no question about these deductions, as they would have the sanction of law and the whims and vagaries of a bureau would no longer govern in the matter.

Federal Farms for Drug Addicts—Back in 1854, Dorothea Dix got a bill

through Congress to set aside 10 million acres of public lands for the care of the insane. The measure was vetoed by President Pierce. A somewhat similar, though less lavish, project for the treatment of drug addicts has now been proposed by Representative Porter. His bill, H. R. 11192, calls for two federal narcotic farms to treat the drug addicts confined in federal penitentiaries. The proposed farms would care for 3000 prisoners. Among many other provisions, the Surgeon General of the U. S. Public Health Service would be required to examine each addict one month prior to his discharge in order to determine whether he had been cured.

Proposed Definition for Oleomargarine—Federal statutes now set forth the different fats and oils used in making oleomargarine and provide that these products are "oleomargarine" if made "in imitation or semblance of butter" or when so made are "calculated or intended to be sold as butter or for butter." According to Representative G. N. Haugen, who has introduced a bill, H. R. 10958, to amend the law, large amounts of fat compounds on the market are being sold without regard to the provisions of the law, as they are put up like butter in pound and even in parchment wrapped quarter pound packages, of a texture and containing moisture similar to that of butter. They also contain salt and some of them have artificial coloring matter, though labelled as "cooking compounds."

Careful research and tests on these products discloses, according to Mr. Haugen, that they do not contain milk or cream and were not mixed or churned

in milk or cream. The dairy and oleomargarine industries alike are stated to be of the opinion that these products are the potential subject of grave frauds. Mr. Haugen therefore proposes to add a third alternative to the definition of oleomargarine, as follows: "or (3) churned, emulsified, or mixed in cream, milk, water, or other liquid, and containing moisture in excess of 1 per centum." This, says Mr. Haugen, "makes a clear, plain, and honest definition, fats sold as fats left alone, fats made to imitate butter all put under the oleo law." A similar bill, S. 3247, has been introduced in the Senate by Senator Norbeck.

Oleomargarine colored in any manner would be subject to a tax of 10 cents a pound, according to an amendment to the Oleomargarine Act of 1886, introduced by Representative Linthicum as H. R. 11848. Mr. Linthicum is quoted as saying that the present law has been circumvented by the discovery of a yellow fat in old cattle which produces a yellow oil and when mixed with oleomargarine makes it look like butter.

Health of the Indians—Stating as one of the whereases that it is claimed that preventable diseases are widespread among the Indian population, that the death rate among them is not only unreasonably high but is increasing, and that the Indians in many localities are becoming pauperized, the Senate on February 2, 1928, adopted a resolution for an investigation of Indian affairs. The expenses, up to \$30,000, are to be paid out of the contingent fund of the Senate.

Contact with the superior civilization of the white man has reduced the number of North American Indians from approximately 1,153,000 pure blooded aborigines to about 406,000, with a high percentage of mixed blood, according to a recent announcement of the Bureau of American Ethnology of the Smith-

sonian Institution. A series of great smallpox epidemics, beginning in 1637, seems to have been the greatest single factor, though war and fire water and other diversions and dissipations of the white race have also played their part.

Other Federal Legislation—A monument to the memory of Major General William Crawford Gorgas in the City of Washington is proposed in a joint resolution, S. J. Res. 92, introduced by the ebullient Senator Tom Heflin of Alabama. The President's physician is as far as ever from getting the rank of colonel, for Messrs. Blanton and two other earnest opponents objected in unison when the bill, H. R. 5658, for this purpose came up in the House on February 6, 1928. A most comprehensive bill, H. R. 10798, to regulate the practice of the healing art in the District of Columbia has been introduced in the House. Hearings on the bill, H. R. 5604, for more hospitals for veterans were concluded on February 4, 1928.

Damages for Typhoid—A claim for \$5000 for damages and \$1000 for expenses has been filed against the city of Cohoes, N. Y., by the father of a girl who contracted typhoid fever, according to *Health News* of New York for February 6, 1928. If the claims were not allowed, the father planned to bring action in court.

This case of typhoid is alleged to have been contracted from water supplied by the city to the home of the girl. The city is called grossly negligent in permitting polluted water from a canal to enter the city's mains through a cross-connection at an industrial plant. This is a violation of the State Sanitary Code. Forty-eight cases of typhoid fever were reported from the general vicinity of this cross-connection.

Court decisions in 8 states have determined that corporations, whether private or municipal, are liable for damages

for injuries or deaths due to typhoid fever caused by polluted water supplied by the corporation to individuals. Since 1910, considerably more than \$50,000 in damages has been allowed by courts and many times that amount unquestionably has been paid in settlements out of court. A comprehensive article entitled, "The Liability for Water-Borne Typhoid," is scheduled for publication in the April issue of *Public Works*.

Milk Ordinance Upheld—Under its police power a city may require producers of milk sold in the city to comply with certain reasonable requirements, even though the dairies are outside the city limits. It is also proper to compel these producers to secure a license, and power may be delegated to the health officer to make inspections for this purpose. These and other important points were decided by the Supreme Court of Oregon in a recent leading case, *Korth v. City of Portland*, 261 Pac. 895.

The facts were that Korth and another dairyman brought suit to restrain the enforcement by the city of a comprehensive milk ordinance, which set forth the requirements for pure milk, provided for licensing dealers, and gave to the health officer the duty of making inspections. These dissident dairymen produced their milk outside the city limits on farms which they admitted did not comply with the requirements, and they sold it in Portland, though having no licenses.

The court held in the first place that the city could regulate the sale of milk within the city and thus the ordinance was not extraterritorial in scope. Although a state law prohibits a city from requiring licenses of peddlers of farm products produced from the soil, the court held in this case that the licenses were merely to cover the expenses of inspection and that such license fee is not levied for peddling. "It is a reasonable provision for the proper inspection and

regulation of the sale of milk within the city. Those who are selling milk are required to register and pay a license, not because they are selling as peddlers, but to insure the proper regulation for the protection of the inhabitants of the city."

The contention that the power conferred on the health officer would allow him to base his requirements on personal whims and caprices was also dismissed by the court as untenable. The Legislature cannot delegate power to make a law, but it can make a law to delegate a power to determine facts upon which the operation of the law depends.

Good Advice from Indiana—A statement worth framing and hanging on the walls of the office of the health department occurs at the beginning of the red covered book of instruction to health authorities issued by the Indiana State Board of Health, of which Dr. W. F. King is secretary. This book contains the public health laws and regulations of the state. The good advice is as follows:

Study the health laws and the health rules. Become familiar with your duties and powers. Don't hesitate or be timid about enforcing the health laws and rules for fear of making enemies. The honest, straightforward officer who enforces law will be respected and honored. If you permit a man to continue to violate the law which it is your duty to enforce, he will despise and ridicule you.

Medical Legislation of 1927—Fifty bills affecting medical licensure and the practice of the healing arts were introduced last year in the various state legislatures, according to a summary in the annual report for the year 1927 of the American Association for Medical Progress, Inc., of New York City. In the 44 state legislatures in session, various efforts were made to obstruct research and to undermine legal standards for medical practice. Attempts to prevent the use of dogs or other animals in medi-

cal research, made last year in New York, Maryland and Minnesota, were killed in committee. Efforts to change vaccination requirements in Massachusetts and New York also failed. Organized local efforts to have children immunized against diphtheria were met in some places with alarming stories of the disasters supposed to have resulted from the use of toxin-antitoxin. These attacks were successfully dealt with by local health officials who supplied the public with the facts.

Bills requiring that applicants for licenses to practice the medical arts be examined in the basic sciences were passed in Nebraska, Minnesota and Washington, though they were defeated in Colorado, Kansas and Oregon.

Miscellaneous—Nearly 20,000,000 cattle were under supervision and over 4,000,000 were on the waiting list for testing on January 1, 1928, in connec-

tion with the coöperative tuberculosis eradication work of the U. S. Department of Agriculture. During December, 1927, there were tested 935,984 cattle, and 18,966 reactors were found.

Present methods and administration of Federal Food Law enforcement are described by W. G. Campbell in the *American Food Journal*, January, 1928.

Rules for packing and labeling of edible oils were issued by the Federal Trade Commission on January 31, 1928.

A national electrical safety code has been issued as *Handbook No. 3* by the U. S. Bureau of the Standards.

A comfort station is not a nuisance *per se* and may or may not be such in fact according to circumstances. This is the holding in *Zey v. Town of Long Beach*, 258 Pac. 492.

The Iowa Supreme Court has held a town liable for polluting a stream. *Stovern v. Town of Calmar*, 216 N. W. 112. This is settled law.

CONFERENCES

April 12-14, American Society of Biological Chemists, Inc., Ann Arbor, Mich.

April 12-14, Federation of American Societies for Experimental Biology, Ann Arbor, Mich.

April 28, National Research Council, Washington, D. C.

April 30-May 2, American Pediatric Society, Washington, D. C.

April 30-May 2, National Probation Association, Memphis, Tenn.

April 30-May 5, National Congress of Parents and Teachers, Cleveland, O.

May 1-2, American Association of Pathologists and Bacteriologists, Washington, D. C.

May 2-9, American Association for Organizing Family Social Work, Memphis, Tenn.

May 10-12, American Association of Hospital Workers, Memphis, Tenn.

May 23, American Climatological and Clinical Association, Washington, D. C.

May 23-26, American Physical Education Association, Baltimore, Md.

May 28-June 2, American Library Association, West Baden, Ind.

May 28-June 7, General Federation of Women's Clubs, San Antonio, Tex.

June 4-9, Biennial Nurses Convention, Louisville, Ky. (American Nurses Association, National League of Nursing Education, National Organization for Public Health Nursing)

July 8-12, Congrès International de la Protection l'Enfance, Paris, France.

July 8-13, First World Congress of Social Workers, Paris, France.

July 16-21, Thirty-ninth Congress Royal Sanitary Institute, Plymouth, England.

October 15-19, American Public Health Association, Chicago, Ill.

BOOKS AND REPORTS

USEFUL BOOKS OF THE PAST YEAR

M. P. RAVENEL, M.D.

OF THE making of books there is no end." During the past year there has been a great flood of books, bearing more or less directly on the teaching of public health. For the benefit of those who are trying to keep up with the advances in public health, we are making an attempt to note briefly the most important books published or reviewed during the past year. Most of these have been selected from the notices in our own JOURNAL, though a number of other leading journals have been consulted freely. We have avoided

mentioning new editions, only one exception having been made.

Specialism has reached even into public health, so the books are grouped loosely into classes. Strict classification is impossible in many cases. Practically all books on hygiene properly give more or less attention to anatomy and physiology, but authors vary in this respect.

Among those in which the body and its functions are primarily considered, there be mentioned *The Human Body*, by Quinor Heaton, E. P. Dutton & Co.; *Anatomical Chest of the Adult and the Child*, by J. A. Myers, Williams and W. Norrell; and *The Human Body*, by Marshall Jones, G. P. Putnam's Sons, and *The Human Body*, by Logan Clendenen, Alfred A. Knopf, Incorporated.

In these days when athletics, especially the intercollegiate form, have become so unduly emphasized, the book, *Heart and Athletics*, by Deutsch and Kauf, translated by Louis M. Warfield, C. V. Mosby & Co., is very timely.

Biographies are always interesting, and no student should miss the opportunity of studying the careers of those who have helped to make science what it is. The following books deserve especial mention: *Life and Work of Sir Patrick Manson*, by Philip H. Manson-Barr and A. Alcock, Wm. Wood & Co.; *Lister As I Knew Him*, by John Rudd Leeson, Wm. Wood & Co.; and *Interpreters of Nature*, by Sir George Newman, Oxford University Press. The one by Sir George Newman contains a number of sketches, biographical and historical, written in an especially interesting style.

The relation of the lower forms of life to disease is constantly attracting more attention. Three books may be mentioned in this connection: *The Biology of the Protozoa*, by Gary N. Calkins, Lea & Febiger; *Host-Parasite Relations Between Man and His Intestinal Protozoa*, by Robert Hegner, Century Co.; and *Protozoology*, by C. M. Wen-

FOR those who have not the time to read their way through mountains of books, even on public health subjects, this bird's-eye view of some of the peaks will serve as a welcome guide. It should not be considered as a detailed chart—not every good book could be mentioned even briefly. However, to help in selection, something good is listed in every major field covered by the public health compass.

yon, Wm. Wood & Co. The last mentioned book is encyclopedic, and its cost is prohibitive to the average man, but every library should have it.

Cancer Control—Report of Symposium at Lake Mohonk, contains material with which all should be familiar.

Carriers are always with us, and we can recommend *The Carrier Problem*, by K. C. Paul, Oxford University Press.

We have frequently commented with approval on the increasing recognition of the importance of oral hygiene. In this field we find: *Pyorrhoea Alveolaris*, by F. St. J. Steadman, C. V. Mosby Co.; *Diseases of the Mouth*, by Sterling V. Mead, C. V. Mosby Co.; and *Dental Education in the United States and Canada*, Carnegie Foundation.

Need for Eugenic Reform, by Leonard Darwin, D. Appleton & Co. is easily the best book which has recently appeared on this important subject.

History is represented by *Peaks of Medical History*, by Charles L. Dana. Paul B. Hoeber, Inc.; and *Introduction to the History of Science*, by George Sarton, Williams & Wilkins Co. The latter is an encyclopedic source book, running from the time of Homer to that of Omar Khayyam.

Professor E. O. Jordan has given us an excellent work, *Epidemic Influenza*, published by the American Medical Association Press, which is a digest of all obtainable literature dealing with the etiology and epidemiology of this disease, which apparently has come to stay with us. In the recent past it has caused the greatest number of deaths throughout the world of any diseases known in history, with the exception of plague.

Several laboratory manuals have appeared, most of which are good, but the large volume, *Standard Methods*, by A. B. Wadsworth, Williams & Wilkins Co., is outstanding. This gives detailed descriptions of the methods in vogue at the New York State Laboratory, of which the author is director.

Hygiene is an all-embracing term, though several clear divisions are recognized. The book *Hygiene*, by Florence Lyndon Meredith, P. Blakiston's Sons, approaches the subject from a number of different standpoints, and is offered as a textbook for students with limited scientific background.

Industrial hygiene, which is assuming a proper place in our program, is well represented by *Personal Health*, by E. R. Hayhurst, McGraw-Hill Book Co.; *Advising the Tuberculous About Employment*, by Hamilton and Kidner, Williams & Wilkins Co.; and *Medical Care of Industrial Workers*, National Industrial Conference Board. For school hygiene, another most important division, we can recommend especially *Fundamentals of School Health*, by James Kerr, MacMillan & Co., which in our judgment, is easily the best single volume that has been written on the subject, and is encyclopedic in character.

Other excellent books are *Health Behavior*, by Wood and Rowell, Public School Publishing Co.; and *Health Supervision and Medical Inspection of Schools*, by Wood and Rowell, W. B. Saunders & Co. Deserving particular mention is the *Handbook on Positive Health*, by several authors, edited by Lenna L. Meanes, Women's Foundation For Health, New York, N. Y. This is a book on personal hygiene, designed especially for women. *Hygiene and Sanitation*, by Jesse Feiring Williams, W. B. Saunders & Co., is an excellent presentation of the subject. An outstanding book in this division is *International Hygiene*, by C. W. Hutt, Methuen & Co., which speaks in international terms, and gives the average reader an entirely new view of the subject. Mental hygiene, a subject which the average health officer and physician have left too much to the specialist, is well represented by *Everyday Problems of the Everyday Child*, by Douglas A. Thom, D. Appleton & Co.

Two excellent books on nutrition, another subject of surpassing importance which is now attracting general attention, are *Your Weight and How to Control It*, edited by Morris Fishbein, G. H. Doran & Co.; and *The Foundation of Nutrition*, by Mary Swartz Rose, MacMillan & Co.

Vaccination against smallpox is considered in an historical scientific survey of the question called *Should We Be Vaccinated?* by Bernhard J. Stern, Harper & Bros., which should convince anyone of the value of the procedure.

The matter of sewage disposal is inseparably connected with the purity of drinking water. A new volume, *Solving Sewage Problems*, by Fuller and McClintock, McGraw-Hill Book Co., is excellent. A second book on this subject, more suitable for the engineer than for the average reader is *The Activated Sludge Process*, by Arthur J. Martin, McDonald & Evans, London.

Two books on the subject of water and its purification are *The Microscopy of Drinking Water*, by George Chandler Whipple, John Wiley & Sons; and *Studies of the Efficiency of Water Purification Processes*, by H. W. Streeter, U. S. Public Health Service. The former of these is a new edition, and is mentioned here because the author is no longer living, and the present volume, edited by his son and others, contains much new material.

While not strictly relating to public health, as such, two books on tuberculosis should be mentioned: *Getting Well and Staying Well*, by John Potts, C. V. Mosby Co.; and *Tuberculosis: Bacteriology, Pathology and Laboratory Diagnosis*, by Baldwin, Petroff and Gardner, Lea & Febiger. The latter is the result of years of experience at Saranac Lake and gives new methods due to Petroff.

It has frequently been pointed out that if we could apply what we already know, life could be made happier and

greatly lengthened. The American Public Health Association has for several years past given much attention to the administrative aspect of public health, and as the result, can now offer *Community Health Organization*, edited by Ira V. Hiscock, which contains revised plans for communities of 100,000 and 50,000 inhabitants, and a new plan for cities of 30,000. Closely allied to this subject are *City Health Administration*, by Carl E. McCombs, MacMillan & Co.; *Municipal and Rural Sanitation*, by Ehlers & Steel, McGraw-Hill Book Co.; and *Clinics, Hospitals and Health Centers*, by Michael M. Davis and others, Harper & Bros.

Some other useful books for general reading are: *Health Problems in Organized Society*, by Sir Arthur Newsholme, P. S. King & Co., London; *Problems of Social Well-Being*, by James H. S. Bossard, Harper & Bros.; and *American Medicine and the People's Health*, by H. H. Moore, D. Appleton & Co. The titles of these books give some idea of their contents. The last is written from the economic standpoint and is a comprehensive review of the cost of medical care and its relation to the public. It has had much to do with the appointment of a committee which is now making a study of this subject. A book which is especially suited to the laity is *Triumphs of Medicine*, by H. S. Hartzog, Doubleday, Page & Co., which tells in non-technical language many of the good things which scientific medicine has accomplished.

Most of our readers are aware of the numerous attempts which have been made for some years past to reorganize the departments of our government in Washington, there being, at present, upwards of forty bodies which deal more or less directly with medicine and public health. Two books give facts along this general line: *Federal Health Administration in the United States*, by Robert D. Leigh, Harper & Bros., and *National*

Government and Public Health, by J. A. Tobey, Johns Hopkins Press.

Advancement in medicine, curative as well as preventive, depends upon research, and since the anti-evolutionists and opponents of science generally are busy, we recommend for general reading, *The War on Modern Science*, by Maynard Shipley, Alfred A. Knopf.

We have made no attempt to include

See Announcement of New Books on pages XXVI-XL

The Human Body—By Logan Clendening, M.D. Illustrations by W. C. Shepard and Dale Beronius and from photographs. New York: Knopf, 1927. xxii + 399 pp., 102 figs. Price \$5.00

Medical information has often been regarded as the peculiar property of the physician, to be jealously guarded by a screen of classic verbiage and hidden under the camouflage of technicalities. Education in medical matters was to be gotten only along the arduous and closely guarded route of premedical, pre-clinical, clinical, and postgraduate years of intense and sustained study. However, the development of the modern sciences tributary to medicine and the advances in the arts of medicine and surgery have now attained such a unification and precision that a presentation primarily for the unprofessional but inquiring reader is both opportune and welcome.

Dr. Clendening's *The Human Body* meets this need. It is first and last an epitome on medical knowledge, with just enough anatomy and physiology to enable the reader to comprehend the normal body in health, whose disorders in disease and old age are the main theme of the work.

The treatment is refreshingly frank and not a few medical idols of confiding patients are tumbled off their pedestals. The natural powers and resources of the body, its own defensive mechanisms, its normal progress into the inevitable stages of senescence emerge ever and

books in foreign languages. Anyone interested will find a number of them reviewed in our columns, as well as in those of other journals. We believe that the majority of our readers are more interested in books using their mother tongue and feel sure that anyone who carefully reads those which have been mentioned will be fairly well posted on hygiene and public health.

again in the discussions of disease and its prevention or cure. It is not, however, intended as a first aid till the doctor comes or a compendium of diagnosis and home treatment, but rather as a background of information on the organ systems in health and in disease which will help the intelligent inquirer to cooperate more effectively with his physician—this in spite of the author's defense of lying to his patients about their true condition.

The discussions of inoculation and vaccination are peculiarly interesting to public health workers, especially the reproduction of the cartoon of 1802 exhibiting the dire results of "cow pock inoculation" in the form of bovine heads and horns growing out upon the terrified victims.

The author is wholly "sold to the idea" of the baneful and all but omnipotent effects of heredity—perhaps a deal more than even the geneticists themselves would admit, as for example with reference to the victim of baldness he says: "He may be sitting in chairs with snake oil and violet lamps playing all over his head, when the only way to cure his baldness would have been to castrate his grandfather."

Possibly the author's amply exhibited antipathy to all forms of social control—except in the matter of vaccination—is back of his rather unguarded statements about syphilis, which he says "has a very hard name—a much worse one than it deserves. It is, after

all, not such a very dreadful disease." He then proceeds to enumerate its disastrous effects, and concludes with the only prescription in the book!

The illustrations are new and they really illustrate in an illuminating fashion. They are often diagrammatic and very clear with the accent on the important features. Those of historical incidents are particularly well chosen and well conceived.

The fact that the author at times lapses into characteristic Baltimorean Menckenesese, especially when he recalls Volstead and vies with Schopenhauer in his view on marriage and its dire consequences may charm some of his readers—but not all of them, for he will have many. In spite of these distractions, the main theme is diseases exposed to public view and its story dramatized, possibly even over-emphasized at times, but always quite readable and informing.

CHARLES A. KOFOID

Modern Methods of Testing Milk and Milk Products—By Lucius L. Van Slyke. (3rd ed.) *New York: Orange Judd Pub. Co. 1927. XII + 344 pp., 53 figs. Price, \$2.00.*

Earlier editions of this book issued in 1906 and 1912 have found a wide use and it seems probable that this completely revised new edition will prove equally useful. The title is somewhat misleading in that the common chemical and physical methods of examining milk are the only methods discussed in detail. After a chapter on the chemistry of milk and one on methods of sampling and of preserving samples for the fat test, five chapters are taken up with a discussion of the Babcock fat test in its various applications and a later chapter (XVI) returns to the same general theme. The Roese-Gottlieb method is given as a means of checking the accuracy of the Babcock test.

Other chapters discuss methods of

determining water in butter and cheese, salt in butter, acidity in milk and milk products. Various simple biochemical tests and methods of testing milk by rennet extract and pepsin are taken up in the next two chapters, followed by a discussion of methods of determining specific gravity, total solids, casein and adulterations. The two chapters on methods of commercial testing, scoring and grading butter, cheese, milk, cream and ice cream are useful but show less familiarity with the latest developments, particularly in the field of grading market milk.

The final chapter giving examples in the arithmetic of milk and milk products helpful to practical workers is followed by an appendix which gives the specifications of standards for the glassware used in the Babcock test drawn up by the Association of Official Agricultural Chemists and the American Dairy Science Association. The United States Government definitions and standards of purity for milk and milk products are also included.

An interesting personal touch is given the book by a frontispiece showing Dr. Stephen M. Babcock, the originator of the fat test that bears his name, reading a fat test in his laboratory. Dr. Babcock's active life spans practically the whole of the experiment station movement in America as he began his work at the New York State Station at Geneva before the Federal Experiment Stations had been established in all of the states. Removing within a few years to the Wisconsin Station where he has since remained, his place was soon taken at the New York State Station by Dr. L. L. Van Slyke. Some of the tables given in this book are those prepared by Dr. Van Slyke in his early work with the Babcock test. These figures still remain the most accurate and comprehensive figures that have been secured for showing the fat present in the milk of various breeds of dairy animals.

R. S. BREED.

Food Infections and Food Intoxications—By *Samuel Reed Damon, A. M., Ph.D.* Baltimore: *Williams & Wilkins*, 1928. 266 pp. Price \$4.00.

This is a reference book which is addressed to food chemists, bacteriologists, physicians and nutrition experts and deals with cases in which food acts as the vehicle by which the infectious agent or toxic material is disseminated. A part only of that limited field is covered as the author narrows his discussion to those diseases in which the transmission of the infectious or toxic substance takes place, as a rule, only through the medium of food. This results in the exclusion of such matters, as for example the transmission of typhoid by shellfish.

In discussing each form of infection or intoxication, the author has presented in considerable detail the phases of etiology, symptomatology, diagnosis, treatment and prophylaxis.

In the introduction to the book there is a short dissertation on the discarded theory that ptomaines cause food poisoning. This might well have been amplified in view of the fact that so many otherwise well informed persons, including physicians and health officers, still persist in seriously giving "ptomain poisoning" as a cause of sickness and death.

The book is divided into three parts. Part I contains chapters on para-typhoid infections from food, tuberculosis from milk and meat, undulant fever from milk, septic sore throat from milk, and actinomycosis. Part II contains chapters on botulism, mushroom poisoning, grain intoxications, milk sickness, potato poisoning, and fish and shellfish poisoning. Part I deals with the ingestion of microorganisms capable of elaborating toxins within the human or animal body. Part II deals with the ingestion of pre-formed toxins.

While the text is well worded, interesting, and easily read and while the discussions of symptomatology and diag-

nosis are, in particular, ably presented, Parts I and II, on the whole, leave a distinct sense of incompleteness. This is not entirely due to the limitations which the author deliberately adopted. Another reason will be sensed from the fact that of 326 references to literature, there are none to work published in 1927, and only 2 and 3 respectively to work published in 1926 and 1925. The chapter on undulant fever is lamentably out of date and presumably was so even before it was printed. It is based on goat's milk, and leaves untouched the highly important matter of cow's milk. A small, but by no means negligible, part of the material in the book appears to be vague and inconclusive, as for example, the evidence presented to support the section on "Poisoning from fish containing a poisonous principle of bacterial origin."

Part III, regarding Zoo-Parasitic Infections acquired through Food, contains chapters on human infection with animal parasites, trichinosis, taeniasis, other parasites of man acquired through food, and diagnosis of helminth infestation, and was written chiefly by Norman R. Stoll, as appears in a rather inconspicuous footnote. This part of the book is distinctly up to date. Of 89 references which it makes to published literature, 1 is for 1927 while 14 and 7 respectively refer to articles which appeared in 1926 and 1925. It contains material of interest and value which, being in such a specialized field, might not otherwise be located by many readers. It is concise, well written and distinctly worth while, even though much of the material may be considered to be chiefly of academic interest in this country.

The proof reading of the book was not perfect by any means. Five typographical errors were noted, of which one, on page 255, naming a specific gravity of 1:200 might be confusing to some readers. The print is clear, the illustrations generally good and the binding is strong.

H. W. REDFIELD

International Hygiene—By C. W. Hutt, M.D., D.P.H. London: Methuen & Co. Ltd., 1927. 261 pp. Price \$3.00.

The author has given us a book entirely unlike most works on hygiene, and one of unusual value. It is true that he writes largely from the standpoint of a comparatively small island country, which is dependent to a great extent upon other parts of the world for its food supply. On account of the enormous shipping interests of England, maritime quarantine perhaps plays a larger part in the protection of that country than of any other, though it is everywhere an important factor. In America it is now entirely under the U. S. Public Health Service, but only a few years ago certain ports and states maintained their own quarantine.

The chapter on International Sanitary Conventions would be interesting under any circumstances, but its significance has been tremendously increased by the introduction of steam vessels and the airplane.

Another question of great international importance is discussed in a chapter under Drug Habits, which gives a rational discussion of one of the most vexed questions with which the public health officer has to deal. Three topics of international interest are Emigration and Immigration, Venereal Disease, and the Health of Seamen, to each of which a chapter is devoted. Industrial Hygiene, as an international question, affects the people of this country chiefly in the importation of hides and fleeces.

About one-third of the book is given to Voluntary Aid, such as the Red Cross, in public health, and the Medical Work of the League of Nations, the latter of which takes into consideration also the Office International located in Paris, and its predecessor, which rendered such valuable assistance to many nations.

The author has given us a volume of great value which should teach us to think of health internationally. The

make-up of the book is excellent and it is written in such an interesting style that one finds it hard to put it down. It can be recommended to all health officers, particularly to those at ports of entry, but can be read with great advantage by sociologists and all others who are interested in the advancement of public welfare. M. P. RAVENEL.

Health Hero Series. 1—Louis Pasteur, 2—Edward Jenner, By Grace T. Hallock and C. E. Turner. New York: Heath. 1928. 238 pp. and 204 pp. Price, \$1.12 each.

The narrative of modern public health can best be told in a series of biographies, for the story of health is the story of men. The recital of the notable events which have resulted in the conquest of disease is, furthermore, particularly suitable for schoolroom use, for in studying the lives of the heroes of health, the youth of the nation receive inspiration as well as instruction. They will get both from these two excellent books, which are fortunate in having as their authors, a trained writer interested in science and a capable scientist.

No more fitting subject could have been chosen to inaugurate this series than the career of the founder of preventive medicine, while that of the first protagonist of vaccination is an acceptable second. This biography of Louis Pasteur is concise, yet complete, and all of the notable episodes in the life span of the eminent scientist are arrayed before the reader. Even the mature sanitarian who desires a succinct account of the greatest of his predecessors in the field of public health could read this little volume to advantage.

The story of Pasteur is more humanly told than is that of Jenner. At times the latter becomes somewhat detailed and often it is a tract on vaccination. This, of course, is not objectionable, except to the ubiquitous anti-vaccinationist, who may fume over it, and the book is packed

with useful information about this one certain preventive of smallpox. The life of Jenner obviously could not be as dramatic as that of Pasteur, for Jenner made only one noteworthy contribution to human progress, whereas Pasteur gave us many.

These two books can be highly recommended for the purpose for which they are designed, as school textbooks. They are attractively and profusely illustrated and printed in a flawless manner. There is a good index in each. It is to be hoped that more books of a similar nature will be forthcoming from the same or equally gifted authors. JAMES A. TOBEY

Your Weight and How to Control It, A Scientific Guide by Medical Specialists and Dietitians—Edited by Morris Fishbein, M.D. New York: George H. Doran, 1927. 260 pp. Price \$5.00.

This book is the outcome of the first Adult Weight Conference, which was attended by 22 physicians and dietitians. It consists of two parts, the first of which is made up of a series of articles which were printed in the *Sunday Magazine* of the *New York Herald Tribune*. The second part gives the Principles of Nutrition, with a series of diets and menus for gaining or reducing weight respectively.

The keynote of the book is that normal weight is closely related to health. The modern craze for reducing is hard-hit in a series of papers showing the irrational ideas held by the majority of people. The effect of reducing irrationally and to too great an extent is discussed from various standpoints, including the nerves, tuberculosis, skin, etc. The dangers of beauty operations and removal of fat are shown, and the many widely advertised mail-order fakes are adequately discussed.

Approximately one-half of the book is given to a clear discussion of the principles of nutrition. A large number of diets, menus and weight tables are

included. The tables give one hundred calorie portions, both in measurements such as the ordinary person uses—tablespoons, cups, etc.—as well as their weight. These weights are apparently given in ounces, though there is no statement to this effect, an omission which should be corrected.

The book deserves a longer review, but the number of authors and contents render this difficult. We can only say further that it is by far the most useful book on this subject for the average reader with which we are acquainted, and we wish for it a wide circulation. It is well printed on light paper with a mat surface, rather a rare occurrence for a book published in America.

M. P. RAVENEL

A Son of Mother India Answers—By Dhan Gopal Mukerji. New York: Dutton, 1928. 112 pp. Price \$1.50.

Mother India was a book of horrors, for which the only excuse could have been a desire to better conditions. The present book has what Miss Mayo's book often lacked, exact references to official documents, which we are compelled to believe disprove many of the statements made in *Mother India*.

The author charges Miss Mayo with misunderstanding, with selecting isolated cases, with suppressing facts which she could have easily ascertained, and even with "untruthful invention." A number of the statements in *Mother India* seemed unbelievable, even before this refutation was published. The authoress is likened to a drain inspector who concludes that the drains are the country. There are also statements from English physicians and from missionaries who assert unhesitatingly that the picture of India given by Miss Mayo is untrue and unjust. One of the worst abuses, the author shows to be due to British official votes. He even shows that one British clergyman voted against one of the reforms, even as late as 1926.

The book on the whole is temperate in tone, especially the latter part of it. The author does not pretend that some reform is not needed in India, but he shows quite plainly that it is somewhat absurd for an American to criticise certain Indian customs, even if they were correctly given. The book closes with several appendices which throw further light on the subject under discussion. Miss Mayo's book excited more than usual attention, which the author characterizes as "a sad commentary on western literature and culture," and we recommend this answer to all who are interested in fair dealing and in the betterment of conditions in India.

M. P. RAVENEL

Playgrounds of the Nation—
By Florence C. Fox, Bull. No. 20. Washington: Dept. of the Interior, Bureau of Education, 1927. 99 pp.

That teachers of civics, geography, nature study, history, and arts and crafts can draw upon the state parks and forests for interesting classroom material is proved by the facts offered in this pamphlet. The text is interesting and the book is profusely illustrated.

Mosquito Surveys. A Handbook for Anti-Malarial and Anti-Mosquito Field Workers—*By Malcolm E. MacGregor, M.A. New York: Wood, 1928. 203 pp. Price \$5.50.*

This 203-page book is described by the author as a handbook for anti-malarial and anti-mosquito field workers. In a broad sense it can hardly be classed as such as it is decidedly limited in information relative to anti-mosquito control measures. In this treatise the author has reported in detail, his investigations on the biology and bionomics of mosquitoes (especially *Anopheles*) of the Island of Mauretius in the South Indian Ocean, about 500 miles east of Madagascar.

The book is arranged in three parts.

The first is devoted to a primary classification of mosquitoes, the anatomy of the egg, larva, pupa and adult, together with their life history and characteristics. There are many interesting line diagrams illustrating this section. Part II is given over to a classification and description of the mosquitoes of Mauritius and Rodriguez. In Part III the author describes laboratory and field technique for the entomologist and field work on mosquito control and research activities.

The treatise is a valuable contribution and commends itself to all interested in mosquito control work. It is to be hoped that in later editions the author will add a fourth part devoted to practical information and reports on mosquito control methods.

ARTHUR E. GORMAN.

Physical Chemistry and Biophysics—*By Matthew Steel, Ph.D. New York: Wiley, 1928. 372 pp. Price \$4.00.*

This book is designed to fill a real need, namely, a text of physical chemistry designed for students of biology and medicine. On the whole it is carefully written, though it seems a bit wordy. Especially Chapter II, on the "Nature and Structure of Matter," seems to contain much material which, considering the present state of our knowledge, might well be omitted. The chapter on "Diffusion and Osmotic Pressure" is better than those found in many elementary books. The treatment is somewhat vague in places, but at least it is not incorrect. The section on "Emulsoids," pages 282 to 310, follows very closely the treatment given by Jaques Loeb.

The fundamental objection to the book as a text in this particular field is the absence of numerical problems. Otherwise it seems to cover the subject completely, fairly accurately and quite lucidly, and it is hoped that in a later edition the lack of numerical problems may be remedied.

ALLEN E. STEARN

Lister As I Knew Him—By John Rudd Leeson, M.D., C.M. (Edin.) M.R.C.S. New York: William Wood, 1927. 212 pp. Price, \$3.50.

The Life of Lord Lister, by Sir Rickman Godlee, will, we believe, always remain the classical work on this great man. However, several shorter books have appeared giving more intimate stories of him as a man, as well as a number of articles, some of which have been reviewed in these columns, and all of which have brought us into closer contact with Lord Lister than the classic mentioned above. Among the shorter books, that by the present author is easily the best. After observing something of Lister's work at Edinburgh, he began as a dresser for him, then became surgical clerk, and remained always a great admirer and friend.

Some very striking contrasts are brought out. Dr. Leeson began his studies in St. Thomas's Hospital, which was in a new and airy situation on the Thames Embankment, where there was much more sunlight than is usual in the City of London. The buildings and apparatus were entirely new, and the hospital was the first to be built on the pavilion system, while the nurses belonged to the institute started by Florence Nightingale. The staff was made up of many of the most noted men in England; yet we are told, "so far as surgery was concerned . . . the old enemies pyemia, septicemia and erysipelas were as rife as ever," though they were generally attributed to overcrowding and dirt. On the advice of Murchison, Dr. Leeson went to Edinburgh where he was greatly distressed by the appearance of Lister's wards. They were gloomy, forbidding and overcrowded, but to his astonishment, he found that the patients were free from pain and cheerful, that there was little suppuration of wounds, none of the dreaded pyemia so common at that time, and that many of the patients seemed to remain in bed only because

there was nowhere else to put them. It soon became apparent to him that Lister's antiseptic treatment, combined with the individual care given to each patient, was the secret of the unusual results.

There is much history in the book, especially concerning the development of antiseptic surgery. The intimate history given of Lord Lister is particularly interesting, and the book fascinates one more than does the larger work of Sir Rickman Godlee.

Some three pages are given to "Aphorisms and Precepts," most of which the author believes were original, but as he says, Lord Lister constantly told his students that this or that was "learnt from Mr. Syme." If the book contained nothing else than these sayings, it would be well worth reading.

It is written in a most fascinating manner, contains numerous interesting illustrations, and is well printed on light paper. We cannot do better than to close by a quotation which contains really the meat of the whole book: "Transcendent as were his epoch-making discoveries, the man was more than the message."
M. P. RAVENEL

Infectious Diseases and Aseptic Nursing Technique—D. L. Richardson, M.D. Philadelphia: Saunders, 1927. 182 pp. Price, \$1.50.

In the first part of the book, one gets a clear cut picture of each communicable disease from the medical aspect—etiology, period of incubation, symptoms and signs, complications, prognosis, and treatment. There is no discussion of the nursing care of the patient in relation to the course of the disease nor of the treatments carried out by the nurse. The diseases are considered with very little reference to community health and to the need for public health education in relation to the prevention and control of communicable diseases, and to the part the nurse plays in this education.

Measures of disease control in home

care of the sick are treated in a general way in one chapter at the close of the discussion of the 28 diseases, but the treatment of these measures lacks the particular applications of principles that would make such a book very valuable.

In the second part, there is an excellent description of the nursing technic carried out in the disease-unit system as practiced in the Providence City Hospital. This detailed account of aseptic procedures would be very useful to anyone who was about to set up this particular technic.

Dr. Richardson's book is very useful as a reference book for the medical aspect of communicable diseases and for one particular type of aseptic procedure in the care of communicable diseases.

OLIVE A. ALLING

Freshman Hygiene. Personal and Social Problems of the College Student—*By Raymond C. Bull, M.D., and Prof. Stanley Thomas, Lehigh University. Philadelphia: Lippincott, 1926. 288 pp. (ill.) Price, \$2.00.*

This book is the outgrowth of extended experience with college freshmen in an attempt to build up the health service on a solid foundation of theory and practice. The text apparently presupposes a perfect blank in the mind of the student so far as concerns any organized knowledge about that portion of the universe which is sometimes called "living." The style does not assume too much in the way of intellectual capacity and may therefore indicate, much as we hate to admit it, that the average intellectual level of college freshmen is lower than is commonly supposed. Two-thirds of the book contains some twenty chapters on the usual topics taught in the high schools under the name "Physiology and Hygiene," and is on the whole sound in its information and in its counsel. The last third of the book, under the title "Social Hygiene," is made up of a dozen

chapters on reproduction, the venereal diseases, and "Civic Aspects of Social Hygiene."

The distribution of the material gives the impression that those in charge of the instruction have not yet sufficiently mastered either the technic of instruction, nor the technic of handling the students so as to integrate the information and the guidance which they offer in a manner calculated to help the student organize his own experience most effectively.

While the contents are on the whole quite acceptable—and quite within the comprehension of high school students, there is a certain formality and there is a certain dogmatism which suggests the need for a more thorough study of the problem of health education from the point of view of modern psychology and pedagogy.

This book should be of great help in institutions which have to rely upon the book for introducing the student to habits, to attitudes, and to information which ought normally to have been assimilated before college age is reached.

B. C. GRUENBERG

Cleanliness and Health—*By Turner and Collins. New York: D. C. Heath and Co., 1926. 263 pp. Price, \$.88.*

This is the second book resulting from the authors' studies and experimental work in health education in the elementary and junior high school grades of Malden, Mass. The reasons for practicing health habits and acquiring health knowledge are carefully set forth from a physiological and biological basis. It is not a text on physiology, but gives a sufficient introduction to the subject in order to make clear the basic reasons for healthful living.

A considerable part of the book is devoted to a discussion of cleanliness in relation to bacterial life as found in soil and dirt, and the prevention of infections. It defines cleanliness as the ab-

sence of dirt, and incidentally of bacterial life. Molds, bacteria, and yeast are described and illustrated, and the work of Jenner and Pasteur briefly told in relation to the origin of vaccination and the science of bacteriology.

Certain important parts of the body, such as the teeth, stomach, intestinal tract, lungs, and the skin are described and illustrated. The prevention of dental decay, the health of the digestive tract and the skin, the prevention of colds, and the control of typhoid fever and tuberculosis are carefully discussed. One chapter is devoted to the care of foods, and another to the harmful effects of alcohol and tobacco.

The book is an excellent text for health instruction in the upper grades and junior high schools, and should be a good guide for teachers who do not depend upon a textbook in the classroom. It is an excellent introduction to a more advanced study of physiology. The book is splendidly written and the material scientifically accurate. Teachers in the upper elementary grades and junior high schools will welcome it.

WILLIAM DEKLEINE

Noxious Gases and the Principles of Respiration Influencing Their Action—By *Yandell Henderson and Howard W. Haggard*, New York: Chemical Catalog Co., 1927. 212 pp. Price, \$4.50.

This book represents a rather novel departure from the usual method of treatment of the subject of poisonous gases. It has generally been the practice to approach this subject from the point of view of the pharmacologist. In the present instance, however, the subject has been approached from the point of view of the physiologist, and Drs. Henderson and Haggard have brought their wide experience in the field of respiratory physiology to bear on this very important problem. The result has been an exceedingly valuable contribution.

The first three chapters are devoted to a general survey of the field and to a discussion of the basic elements of respiration and its control. A chapter deals with the various physical laws relating to gases and vapors. The absorption, distribution and elimination of volatile substances are discussed in a general way. The various types of noxious gases are considered, and prevention and treatment of poisoning are treated.

There has long been a need of a book such as the one under discussion, for here instead of considering the gases from their chemical viewpoint they are regarded and classified from the point of view of the action which they bring about in the human body. Accordingly, the gases have been classified as asphyxiants, irritant gases, volatile drugs and drug-like substances, and inorganic and organo-metallic gases. In each group the various gases are rather completely discussed from the point of view of toxicology with tabulations showing the various physiological and toxicological effects as obtained from the literature. With the exception of benzol the discussion seems to be admirably handled. In the case of this substance, however, it would appear that the authors have failed to make complete use of the report which was recently published by the National Safety Council.

Each chapter closes with a bibliography of pertinent references.

LEONARD GREENBURG

Body Build: Its Development and Inheritance—*Bull. No. 24 Eugenics Record Office*—By *C. B. Davenport*. Cold Spring Harbor, N. Y.: 1925. 42 pp.

This pamphlet is an abstract of a volume of the same title, Publication No. 329 published by the Carnegie Institution of Washington. This abstract has been prepared so that the study contained in the original volume will be available more easily for students and workers in the field of eugenics.

Some Administrative Aspects of Scarlet Fever—*Reports On Public Health and Medical Subjects No. 35. Being a report on current English public health practice in the control and treatment of Scarlet Fever, prepared by Allan C. Parsons, M.R.C.S., with the assistance of a Committee of Medical Officers of the Ministry of Health, from materials furnished, in large part, by Medical Officers of Health and Superintendents of Isolation Hospitals.* London: Published by His Majesty's Stationery Office, 1927. 368 pp. Price, \$1.80.

This report shows the thoroughness with which the English are accustomed to study things, and the conclusions are characteristically conservative. The meat of the whole report is summed up in the prefatory note by Sir George Newman.

Neither the cause of nor immunization against scarlet fever is considered, though the opinion is expressed that "immunization, natural or acquired, is the biological answer to disease."

The minimum period of detention varies in the sixty hospitals investigated, from 28 to 42 days, though the Metropolitan Asylums Board seems to favor a longer period. In Brook Hospital, 67 days was the average in 1924. The tendency in America, especially since antitoxic serum has come into use, is to shorten this period. The English board concluded that as a routine procedure, 4 weeks for uncomplicated cases was long enough. In other cases, the period of detention must be determined by the presence of discharges, general health, etc. The board does not regard the discharge of patients in the late stages of desquamation as a danger to public health.

In England the detention hospitals are overcrowded, and it is believed that too much space is taken up with scarlet fever. From 1917 to 1926 inclusive, there were only 10,672 deaths from scarlet fever, though during the same period, there were 58,292 deaths from measles,

392,942 from pneumonia, and 13,645 from epidemic diseases affecting the central nervous system. It is clear that the old dread of scarlet fever still affects the public as well as the medical profession. These considerations have led to a study of home treatment, and the board concludes that the latter has not received the attention which it deserves.

Terminal disinfection has been discontinued by certain officers, and it is shown, quite conclusively we think, that neither disinfection by steam nor fumigation, nor a combination of the methods, has any value in lessening the number of secondary cases. Fairly extensive studies have shown that hemolytic streptococci are found in the throats of many patients and may retain their vitality under conditions simulating those of the sick room for 50 days. It is pointed out, however, that scarlet fever is seldom conveyed by inanimate objects, and the very rational conclusion, which has been preached in this country for a number of years, is that current rather than terminal disinfection is the efficient method. Sterilization of food utensils and the destruction of remaining portions of foods are advised.

The report can be especially recommended to health officers and those engaged in any way in the prevention of disease.

M. P. RAVENEL

The Rise and Fall of Disease in Illinois—*By Isaac D. Rawlings, M.S., M.D., in collaboration with William A. Evans, M.D., D.P.H., Gottfried Kochler, M.D., and Baxter K. Richardson, A.B. Graphs developed and drawn by A. F. Dappert, and pictures of many persons associated with the story. Indexed by Clara Breen. Springfield, Ill.: Schnepp & Barnes, 1927. 432 pp.*

This volume has been issued in commemoration of the fiftieth anniversary of the founding of the State Department of Public Health of Illinois. It falls naturally into two parts, the first of

which treats of health conditions as far back as is permitted by the history of the state and the records. The second is devoted to conditions since the founding of the State Board of Health, and the establishment of correct records.

The introduction gives a brief, but interesting history of the territory itself. The history of men's struggles against the forces of nature is always interesting, especially when they are pioneers winning new lands for cultivation and settlement. This story has particular interest for the members of our Association, as John Henry Rauch was a member of the first Board of Health of Illinois, organized July 12, 1877, on which he served until 1891, his death occurring some three years later. He served first as secretary, then as president of the board, and as told in *A Half Century of Public Health*, was an unusually active man, not only in his health activities, but also in research. He was throughout his connection with the state board "easily the central figure of public health machinery and thought in the state."

Dr. Rauch was the fourth president of the American Public Health Association, his election having taken place in 1877.

The volume carries us through struggles of a midwestern state, much of which was in a district infested with malaria, and on account of its situation, subject to water-borne diseases. It is the story of a successful struggle of science against nature, directed by men with ideals as well as energy.

There are many biographies of the pioneer workers, all of whom played their part in the creation of health sentiment throughout the state, and in the establishment of a board of health which is recognized as one of the best in the country.

The book as a whole is really a history of preventive medicine, beginning about the time when bacteriology was coming to be such a potent factor in

health work. It is well and interestingly written, abundantly illustrated, and well put together as a permanent record. It can be cordially commended to all who are interested in public health work.

M. P. RAVENEL

The Canadian Mothers Book, Mothers Series, No. 1.—By Helen MacMurchey, M.D. Issued by the Department of Health, Ottawa, Can. 163 pp. Obtainable upon request.

It would be difficult to find a better baby book than this little paper-covered *Blue Book* of 163 pages including the excellent index. It is up-to-date to the least detail and covers in a most pleasing manner the essential points in maternal and child care.

One point in particular is worthy of note and something it would always be well to remember in preparing books for mothers, that is: the reiteration of the father's share in the home. The appeal to sentiment of the right sort is well done but not overdone, and the positive note throughout, a great improvement on the old way of multiplying "don'ts" for parents.

In matters of diet a few items are interesting and a bit out of the ordinary. A salt-free diet the first week of every month after the fifth is advocated. Cod liver oil for pregnant mothers as well as for the baby is recommended.

Proper care of cows to produce the best milk for babies and the necessity of fresh air and sunlight for herds are duly emphasized.

Many things are mentioned which are most helpful to mothers and rarely covered, such as a list of "presents" for the new baby and knitting directions for various useful articles in the baby's wardrobe.

A standard weight chart is included with the book and the attractive photographs of "real" children add much to the general make-up.

MERRILL E. CHAMPION

The Teeth and the Mouth—
By LeRoy L. Hartman, D.D.S. New York: Appleton, 1927. 93 pp. Price \$1.50.

This little volume is essentially a primer for the mass of grown-ups for whom oral hygiene and the art of dentistry is either a jumble of half truths and superstition or an entirely closed book. In question and answer form the author treats some 116 queries which the layman might properly desire knowledge upon, in simple, easily understandable language. The subject is considered from the point of view of the infant (and its mother) up to 6 years of age, the school child period, and the period of

adult life. The subject is surprisingly well covered in a non-technical way in these few pages, though still more emphasis on the importance of preventive dentistry (with a discussion of how preventive dentistry differs from palliative or curative dentistry) might have been expected.

The book would have been improved by a brief interesting statement emphasizing the present status of oral hygiene and pointing out that the chief hope for the future lies in early preventive dentistry. A short glossary of the few inevitable technical words would have been a valuable companion to the excellent index. PHILIP S. PLATT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Carbon Arc Irradiation—Systematic irradiation with the carbon arc had no effect in reducing the incidence of colds—an experience comparable to that with the mercury vapor light. There was only slight pigmentation of the skin.

BARENBERG, L. H. Effect of Carbon Arc Irradiation on Infants. J.A.M.A., 90:7 (Feb. 18), 1928.

Dangerous Dieting—An ample and balanced diet is the plea of this paper inveighing against the alleged dangers of dieting. According to the bread bakers "normal appetites are the best determinators of the kind and amount of food required," a statement which we doubt.

BARNARD, H. E. The Trend of Nutritional Science. Boston M. & S. J., 197:31 (Feb. 2), 1928.

Occupational Effect Upon Sickness Rates—This is a report on the frequency of sickness of one or more

days' duration covering a period of three years. Detailed statistics by occupation, age, sex, and length of service are presented.

BRUNDAGE, D. K. Sickness Among Persons in Different Occupations of a Public Utility. Pub. Health Rep., 43:6 (Feb. 10), 1928.

Minor Mental Disorders—A test of a large number of industrial operatives in England indicates that a large proportion of the population suffer from minor psychoses which, in some industries, result in considerable loss of time.

CULPIN, M. Incidence of the Minor Psychoses. Lancet, 1:5 (Feb. 4), 1928.

Are Vacuum Cleaners Dangerous?—A typically thorough British inquiry into the possible public health menace of the vacuum cleaner. Dust impregnated with bacteria was found to pass the filter bag in sufficient amount so that the same bacteria could be recovered

from the filtered air. What this proves is not quite clear, but it is hoped that the terrifying evidence will not prove a deathblow to this useful household appliance.

EYRE, J. W. H. Vacuum Cleaners and the Public Health. Med. Off., 39:3 (Jan. 21), 1928.

Ventilating Dairy Barns—This is a discussion of the relative merits of the King, Rutherford, and Fairbanks systems of natural ventilation of dairy barns, which should be known to all health officials concerned in dairy inspection. N. Y. State College of Agriculture Extension Bulletin No. 151 covers the subject.

FAIRBANKS, F. L. Dairy Stable Ventilation. J. Am. Soc. Heat. & Vent. Eng., 34:2 (Feb.), 1928.

Examination of "Well" Patients—"What a 'well' patient thinks about" might be the topic of this paper (with apologies to Briggs), which should prove interesting to all health officials who are concerned in any way with health examinations.

FITZ, R. Clinical Observation on "Well" Patients. Boston M. & S. J., 197:31 (Feb. 2), 1928.

Scarlet Fever Variants—This paper presents a table of distinguishing clinical features to be used in differentiating between morbilli, rubella, true scarlet fever, para-scarlet A, and para-scarlet B.

FRIEND, G. E. Some Cases of a Scarletiform Type. Lancet, 1:6 (Feb. 11), 1928.

Testing for Typhoid Immunity—The filtrates of *B. typhosus* produced an allergic reaction in immune patients and a negative reaction in apparently susceptible persons. The authors suggest the test as useful in determining if immunity has been established in an individual.

HOWELL, K. M., and CORRIGAN, M. Skin Reactions with Bacterial Filtrates of *B. Typhosus*. J. Infect. Dis., 42:2 (Feb.), 1928.

Young Women and Tuberculosis—The failure of the tuberculosis rate to decrease as rapidly among women as among men of the same age group is laid to the desire for a boyish figure, improper diet, flimsy dresses, thin stockings, tight brassieres, slouchy posture, cigarette smoking, insufficient sleep, unhygienic environment, too infrequent examinations, too much study. The only possible factors the author seems to have omitted are gin or petting parties.

KNOPE, S. A. Tuberculosis Among Young Women. J.A.M.A., 90:7 (Feb. 18), 1928.

Experimental Pellagra—Dogs fed a pellagra-producing diet developed a condition indistinguishable from the disease known as black tongue.

GOLDBERGER, J., and WHEELER, G. A. Experimental Black Tongue of Dogs and Its Relation to Pellagra. Pub. Health Rep., 43:4 (Jan. 27), 1928.

Measles Control—A rational plan of preventing infants from being exposed to measles infection is offered as an emergency program for any community facing a measles epidemic.

HOILES, B. S. Measles a Community Emergency. Pub. Health Nurse, 20:2 (Feb.), 1928.

A Resurvey of Cincinnati Thyroids—Three years after the original survey a considerable reduction of moderate and marked goiters was found, and the age incidence was lower. Iodized salt and more interest on the part of parents and physicians are given as the causes.

OLESEN, R. A Resurvey of Endemic Thyroid Enlargement in Cincinnati. Pub. Health Rep., 43:3 (Jan. 20), 1928.

Antityphoid Vaccination—The value of antityphoid vaccination is shown not only in the experience in protecting the navy personnel but in the Virgin Islands as well. The author asks why we should not require general vaccination: there are several reasons why we do not, which are generally appreciated by health officials.

PRYOR, J. C. Antityphoid Vaccination in the United States Navy; Experience of 14 Years. *U. S. Nav. M. Bull.*, 26:1 (Jan.), 1928.

Newspaper Publicity—Why a case of communicable disease is news, and how the item should be utilized is the burden of this abstract.

SLEE, R. *Modern Health Officers*. New York State J. Med., 28:3 (Feb. 1), 1928.

Intradermal Smallpox Vaccination—A valuable record of 2769 primary vaccinations, 97.8 per cent of which were positive. The intradermal method of administration has so many advantages and is so clearly the most efficient method that any other should be prohibited for group application.

TOOMEY, J. A., and HAUVER, R. B. Intradermal Vaccination. *Am. J. Dis. Child.*, 35:2 (Feb.), 1928.

Cattaraugus Infant Deaths—The gratifying decline in infant death rates

in Cattaraugus County during the demonstration was almost wholly due to decreases in deaths from the communicable diseases. In the same bulletin is a notice that the county health work will be continued along essentially the same lines by the County Health Board, despite the opposition of the Medical Society.

WIEHL, D. G. Infant Mortality in Cattaraugus County. *Milbank Quarterly Bull.*, 4:1 (Jan.), 1928.

Nursing Visits—This second installment of a discussion about measuring nurse power presents many interesting conclusions. One nurse per 2250 urban or 3300 rural population is suggested. Opportunities for extended study of nursing problems are numerous.

WINSLOW, E. A. More About the Measurement of Nurse Power. *Pub. Health Nurse*, 20:2 (Feb.), 1928.

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

National Federation of Day Nurseries—A report of the conference of this organization held in May, 1927, is worthy of careful study by anyone interested in child welfare problems. The report itself has been carefully prepared and printed, and the contents give much valuable information regarding several important subjects, including habit training, health problems, and varying types of nurseries. The biennial report of the president is stimulating, and indicates a broad conception of the problem of day nurseries. Modest reference is made to the recent publication of a new dietary for use in nurseries. A careful study of this dietary suggests that it would be exceedingly useful by many groups concerned with child welfare clinics and nutrition classes. "Nowhere is the spirit of progress more evident than in the growing concern of society for the well-being of the children. . . . There is a larger recognition than ever before of the fact that the future of the State depends upon the child of today. We, of the Federated Day Nurseries, must lead in the solution of all such problems as come properly within our province."

New Orleans—Bound in light blue covers, and occupying 127 pages, the biennial report of the health board of the Parish of Orleans and City of New Orleans presents a comprehensive picture of the work during 1925 and 1926. The crude death rate for white persons was 14.53 and for colored persons, 29.06, and for all persons combined, 18.32, in 1926. During the year, 2 cases of bubonic plague were reported, both being Japanese seamen, sick at the time of arrival.

Immunization measures were inaugurated to prevent diphtheria and scarlet fever in orphan asylums and in child

welfare clinics. Health department expenditures for the year 1926, according to a classified statement, amounted to \$234,319, an increase of over \$7,000 over the previous year. The population in 1926 is recorded as 433,000. One of the features of the report is a table showing the number of deaths; population, and death rates by years, beginning with 1787.

Mosquito Extermination Commission—The 15th annual report of the Atlantic County (N. J.) mosquito extermination commission reviews the work of the 1927 season and is illustrated with several excellent photographs. The problems and possibilities of a mosquito extermination program are set forth in a manner to interest both laymen and technical workers in the field. It is stated that the salt marshes of New Jersey cover approximately 200,000 acres and account for many millions of two species of salt marsh mosquitoes. Heavy mosquito breeding follows abnormal, high tides, when the water brought up is not all drained off on the low tide but remains in the holes and depressions or on the meadow surface. This commission is evidently carrying on an active and successful extermination campaign. The total footage of new ditches for the year was 578,225 feet, making a total footage to date of over 10 million feet.

National Dairy Council—Methods of health education employed by the council in various parts of the country are described in the last annual report. In its educational work, emphasis has long been given to health as the great objective. Optimism is a keynote in this record of progress during a 7-year period. On the basis of Department of Agri-

culture figures, it is calculated that the per capita consumption of milk and its products during 1926 were 24 per cent greater than in 1920. Seven per cent fewer cows gave 34.7 per cent more milk than in 1920.

The work of the council was first concentrated, to a large extent, in schools. As the organization of these activities has become perfected, the work has expanded to reach adult groups. The nutrition department functions through different types of health and welfare agencies, coöperation having been established, for example, with 35 health departments in 25 states. There were supplied material, projects and exhibits to emphasize the need of proper diet, and the observance of the health rules. It is gratifying also to note that the need of pasteurization has been emphasized.

Racine, Wis.—Racine's annual report of 50 mimeographed pages again illustrates how an attractive and enlightening report may be prepared at a reasonable cost. The report is bound in heavy paper covers with an attractive front cover. Blue prints show graphically the birth and general death rates and important specific death rates from 1916 to the present time; and also the results of the appraisal of city health activities. A table of contents and a health organization chart precede the main report. Another noteworthy feature is a tabular statement showing time distribution in nursing service by years, 1924-1927. One page is devoted to a classified budget statement for each year, 1924-1928.

This city of 71,300 people records a birth rate of 20.6, a death rate of 8.2, and an infant mortality rate of 50.4.

Under educational activities it is noted that 505 news stories were carried in two daily papers, while 51 lectures and public addresses were given, in addition to various magazine and other health articles. In coöperation with the tubercu-

losis association, there were prepared a pamphlet entitled "The Heart of the Business," dealing with physical examinations, and a booklet entitled "Tuberculosis—The Maker of Orphans" (for enclosure in the Christmas seal solicitation letters). The diphtheria booklet was revised, and a smallpox vaccination leaflet was prepared, entitled "When Great-Grandmother was a Little Girl." An active campaign to educate factory workers in health was launched during the year. This is an excellent report, carefully prepared, and well balanced as to statistical tables and descriptive text. It is a record of activity for a city of its size.

May Day—The Goal of May Day—A Year-round Program—is a little book published by the American Child Health Association, which gives a comprehensive child welfare program. Parents, teachers, pastors, social workers, all interested in children, will find suggestions of programs to promote the health and happiness of children in every walk of life. It is an attractive, well illustrated book, concisely and clearly written. The question and answer method is used in exposition with good effect. The importance of the school health program is stressed, with suggestions and illustrations, and the necessity of coöperation and coördination of home, school and community is brought out. Of considerable value are the bibliographies attached to various chapters, which should be stimulating to further study.

May Day, Child Health Day, is the title of the compilation of child health programs for 1927 throughout the country. To quote: "May Day was recognized and celebrated in every state in this country and in Hawaii." There were 50 May Day chairmen, and of these 36 were officials of the state boards of health. "May Day not only pours into the official health machinery of the country new currents of activity, but it serves

to interpret to a community dramatically and visually the work and aims of public health officials for the protection and encouragement of child life."

A list of the national groups cooperating includes state and government departments, lay groups such as Parent-Teacher Associations, League of Women Voters, American Federation of Labor, etc. Youth groups and, in fact, many important national organizations are listed. Abstracts in brief of the activities of these organizations, churches of various denominations, and lastly of the state programs are given. This is interesting as a record of what was done last year on May Day—also as a guide for what may be undertaken by these organizations and others this year to encourage child health.

Commonwealth Fund—The 9th annual report of the Commonwealth Fund describes the efforts to improve the physical and mental health of American children. An expenditure of \$1,953,557 last year for this purpose and for hospitals, educational and welfare work is recorded.

A 5-year demonstration of health work in Fargo, N. D., was completed and the city has made provision for the continuance of every essential activity at its own expense. Fargo's health budget for 1928 calls for an expenditure of \$1.13 per capita for health purposes as compared with \$.28 in the year prior to the opening of the demonstration. The health work of the city is rated by the American Public Health Association at 814 points out of a possible 1,000 as compared with 320 the year before the demonstration. Similar demonstrations are being continued in Rutherford County, Tenn.; Athens (Clarke County), Ga.; Marion County, Ore.; and the official scoring of public health activities in these communities already shows gains comparable to that in Fargo.

In Austria where the Fund has aided

in the support of various forms of child welfare and health work throughout the post-war period, no attempt has been made to import American public health methods, but standards of existing Austrian child health service have been raised and various extensions of the public health program have been made in accordance with the demands and understanding of each community. In the belief that the best way to improve standards is through the training of workers in strategic points throughout the country, scholarships totaling \$39,000 have been given to physicians, midwives, and welfare workers.

The Fund's program for the development of child guidance clinics, visiting teacher work in the public schools, and allied projects in the field of mental hygiene is noteworthy. A 5-year period of demonstrations and consultant service under this program, ending in June, 1927, has resulted in the establishment of community clinics for the study and treatment of children's behavior problems in Cleveland, Philadelphia, St. Louis, St. Paul, Minneapolis, Dallas, Baltimore, Richmond, Milwaukee, Los Angeles, and Pasadena. Following a series of 3-year demonstration, together with advisory and consultant service, visiting teacher work has been organized in the public school systems of 58 communities located in 32 different states. School children to the number of 15,439 have been aided by visiting teachers in the solution of their difficulties in these demonstration centers and in New York City.

An outstanding feature of the Fund's mental hygiene program was the establishment this year of an Institute for Child Guidance in New York City. This Institute is fully equipped both for research and for practical work with children who exhibit conduct disorders and personality difficulties. It also provides a center for the special training of psychiatrists, psychologists, and psychiatric

social workers. Fellowships established by the Commonwealth Fund for students at the Institute are administered by the National Committee for Mental Hygiene, the New York School of Social Work, and the Smith College School for Social Work.

For the development of rural hospitals the Commonwealth Fund appropriated \$414,000 during the year under review, making awards to Farmington, Me.; Beloit, Kan.; and Wauseon, O. Farmville, Va., and Glasgow, Ky., had received awards the previous year under this program, the objects of which are to provide modern hospital facilities in rural areas where they are needed, to assist in improving standards of local medical practice, and to provide an incentive for good physicians to remain in the country and for young physicians to go there. In accordance with a policy of coöperation which is applied so far as possible in all the Fund's local work, it is stipulated that the community shall pay a third of the cost of building and equipping the hospital and shall undertake its maintenance. The general plan includes the construction of 50-bed general hospitals in the selected areas, the development where advisable, of facilities for the training of nurses; provision for preventive and educational clinics as a part of out-patient service; fellowships to local physicians for post-graduate study; educational institutes and clinics for physicians; and the development of community public health activities in coöperation with the hospital.

Medical Education—The second report of the commission on medical education deals with the training and opinions of successful practitioners, the demands on medical practitioners, the opinions of state medical boards, and

with medical school data. It is indicated that a large majority of physicians and educators who are familiar with the problem of medical education in the United States and Canada are evidently of the opinion that the general features of present medical training compare favorably with those in other fields of education and that great improvement has occurred in recent years.

It is stated that the regulations which have probably been most important in the improvement of medical education and which are large factors in the present rigidity and overcrowding are the requirements of each state for medical licensure. The primary function of licensure is to determine the fitness of the individual to practice medicine. The chief factors determining that fitness are the character, industry, and ability of those who study medicine and the character of the medical training. Twelve states now require an internship for licensure to practice and some medical schools require the internship for the degree of Doctor of Medicine.

In regard to the medical course, it is stated that "extensive lecturing and operative clinics for large groups are criticised by some, although their use has been greatly reduced. It is the current belief that time can be more profitably spent in reading or in elective work and that lectures should be confined to the general exposition of the principles of given subjects and to suggestive correlation of the various fields of study rather than to the presentation of subject matter." It is further stated that the selection of the teaching personnel of medical schools is considered by some to be as important as the selection of students. The vital influence of stimulating teachers who are masters in their individual fields can hardly be overestimated.

NEWS FROM THE FIELD

NEW TEXAS SEWAGE SECTION FORMED

AT the January, 1928, meeting of the Texas Section, Southwest Water Works Association in Houston it was voted to form a sewage division within the association for the purpose of advancing sewage research, and then admit a broader discussion of sewage treatment problems as they affect this state.

W. S. Mahlie, in charge of the Fort Worth Water and Sewage Purification Plants, was appointed director of this sewage division. Membership in this section entitles the member to a copy of National Sewage Research publication which is to contain papers of national importance along the various lines of sewage treatment. This publication is to be issued four times a year. Membership dues for the section are \$1.00 per year and can be mailed to Mr. Mahlie at Fort Worth.

The first issue of the national publication is to be off the press July 1 and it is, therefore, desired that all those who wish to take membership in the section make their remittances to Mr. Mahlie promptly in order that he may send the list of members to the national office so that they may receive the first copy of the publication.

BUDAPEST CONFERENCE

EMERY R. Hayhurst, M.D., Fellow A.P.H.A., Ohio State University, Columbus, O., and Fred H. Albee, New York, N. Y., have been appointed Joint Chairmen of the National Committee for the United States to the Fifth International Medical Congress of Industrial Accidents and Occupational Diseases to be held in Budapest, Hungary, September 2-8, 1928. Richard Kovacs, M.D., New York, N. Y. has been appointed

Secretary of the United States committee. Dr. Hayhurst, secretary of the Industrial Hygiene Section of the A.P.H.A. will present a paper at the Budapest meeting.

PURE FOOD CONFERENCE

CHIEF food inspector S. T. Pyper, of the Cincinnati Board of Health, has been elected chairman of the Cincinnati Pure Food Conference. The conference is an organization meeting of a group that is expected to be influential in enforcing the pure food and drug acts in Ohio, Indiana and Kentucky. The conference will meet quarterly.

HOSPITAL WILL CLOSE

THE trustees of the New York Infirmary for Women and Children, 321 E. 15th St., New York, N. Y., founded in 1853 by Dr. Elizabeth Blackwell, have voted to close the institution on July 1. The reason given is that the mounting deficit of the institution is too heavy to carry. No announcement has been made as to the future disposition of the hospital's assets. The last report of the United Hospital Fund (1926) put the assets at \$1,354,697, about equally divided between property and investments. The income that year amounted to \$170,044 of which \$95,643 was earned and the total expenditures of \$196,847.

MALARIA INCREASES IN NEW MEXICO

DURING the past year there has been a marked increase in the number of malaria cases in Doña Ana County, N. M. Dr. C. W. Gerber, county health officer, prepared a report covering the situation and made definite recommendations to the county commissioners regarding the control measures to be taken. The county was unable to

finance any work this spring so the commissioners appealed to the State Board of Public Welfare for aid. As a result of this appeal, the Board of Public Welfare has borrowed \$2,500 on the credit of the state to be advanced to Doña Ana County. This money is to be used to finance necessary control measures until July 1, when the county will be able to make a levy to do the work itself. Measures to be taken include planting of top-minnows, dusting with Paris green and quinine administration.

NEW YORK STATE CANCER LABORATORY TO RECEIVE LEGACY

THE New York State Institute for the Study of Malignant Diseases is one of three organizations which will benefit by a trust fund of \$100,000 left by C. P. H. Shoellkopf of Buffalo, N. Y.

RESEARCH ON SLEEPING SICKNESS

AMONG the awards made by the John Simon Guggenheim Memorial Foundation to American scholars, scientists and artists is the fellowship granted to Dr. Warren K. Stratman-Thomas, research pharmacologist of the University of Wisconsin, for research for a satisfactory drug for treatment of sleeping sickness. Dr. Stratman-Thomas who will work with Dr. Clement C. Chesterman in the Belgian Congo, will endeavor to determine by clinical trial the therapeutic value of 6 new arsenical compounds in the chemotherapy of animal and human sleeping sickness.

PUBLIC HEALTH DISCUSSED BY MEDICAL GROUP

AT the annual meeting of the Medical Society of New York State to be held at the State Armory, Albany, N. Y., May 21-24, a section on public health has been arranged. The following program will be given:

May 22—The Source of Brucella Abortus Infection in Man, Charles M. Carpenter, M.D.,

Ithaca; Social Hygiene in Mississippi Flood Relief, Albert Read, M.D., Albany; Whooping Cough, Edward S. Godfrey, Jr., M.D., Albany; Public Health Work by County Medical Societies, Guy Turrell, M.D., Smithtown Branch.

May 23—Corrections of Physical Defects in School Children in Small School Systems. David C. McKenzie, M.D., Granville; 1928 Medical Legislation, Paul B. Brooks, M.D., Albany; Methods in Obtaining Milk Code Adoption, Hilton J. Shelley, M.D., Middletown; Laboratory Control of Milk Under New State Code, Morris Maslon, M.D., Glens Falls; Control of Impetigo Contagiosa, Ellis Kellert, M.D., Schenectady.

Dr. Leo F. Schiff, health officer of Plattsburg, is chairman of the section and Dr. William L. Munson, district state health officer, is secretary.

PASADENA'S HEALTH TOURNAMENT

A tournament of Health Week in Pasadena, Calif., April 29-May 5, has been announced by Dr. Warren F. Fox, city health officer. Special days are given over to safety first, child hygiene, hygiene, hospitals, and health education. The program will be concluded by a health parade.

MEDICAL JOURNAL CHANGES NAME

WITH the February, 1928, issue, the *Boston Medical & Surgical Journal* appeared as *The New England Journal of Medicine*. In commenting editorially upon the change of name of the journal, which had its origin in 1828, when the *New England Journal of Medicine and Surgery* and the *Boston Medical Intelligencer* amalgamated, the statement is made: "The times have changed and the sphere of usefulness of the Journal has widened and today the same Journal, under a new name opens its one hundred and ninety-eighth volume."

SAFEGUARD HEALTH IN BUILDING INDUSTRY

IN its program for the future the new aim of the American Institute of Architects will foster country-wide health and safety in the building indus-

try, according to a statement made recently by D. Everett Waid, past president of the institute and a member of the committee. Committees are coöperating with the Building Trades, Employers' Association, the Workers' Health Bureau and other organizations to safeguard life and overcome the great economic waste.

BETTER HEALTH SPECIAL

THE Missouri Pacific "Better Health Special" which for 28 days in January and February toured the state of Texas promoting health education in the 110 towns visited, proved to be an effective means of disseminating health facts. It is estimated that approximately 70,000 persons saw the exhibits and heard the lectures. The Health Special personnel included representatives of the U. S. Public Health Service, the U. S. Department of Agriculture, the State Departments of Health of Texas and Louisiana, and also railway surgeons, sanitarians and city health officers. The train was provided through the generosity of L. W. Baldwin, President, and H. R. Safford, vice-president of the Missouri Pacific Railroad.

NUTRITION BASIS OF MEMBERSHIP DRIVE OF SOUTHERN CALIFORNIA PUBLIC HEALTH ASSOCIATION

AS an opening drive for membership, the Southern California Public Health Association was fortunate in securing the services of Dr. W. D. Sansum, author and noted expert on foods and metabolism. Dr. Sansum is the author of *The Normal Diet* and the head of the Potter Metabolic Clinic at Santa Barbara. As a contribution to the advancement of public health in Southern California, he is giving a series of four lectures, the first of which was delivered February 24 on "Acidosis in Relation to Errors in Diet." The association has an associate membership of nearly one hundred.

Owing to the fact that Los Angeles County produces annually about \$90,000,000 worth of food products, and nutrition has such a close relationship to public health, the association believes much greater attention should be given this subject than has been the practice in the past. It hopes to develop a close relationship between the large corporations engaged in handling food stuffs and the Southern California Public Health Association.

A committee, of which Dr. Warren F. Fox, Health Officer of Pasadena, is chairman, has been engaged in making a study relative to the subject of milk in relation to the spread of communicable disease, and will soon present its report. Recent agitation throughout the country on the subject of whether all milk should be pasteurized has made this committee necessary.

Pasadena is now housed in her own Civic Center, costing well over \$1,000,000 and the Health Officer is occupying a new suite of offices, which places Pasadena in the forefront with one of the best equipped departments in the United States.

Ground was broken for a new \$75,000 County Health Center on February 14 in the City of Santa Monica, which city has affiliated with the County Health Department of Los Angeles County. Dr. William Reasner, formerly associated with the Health Department of Minneapolis has been appointed by Dr. J. L. Pomeroy as Health Officer of the Santa Monica District.

Great interest is being shown throughout Los Angeles County by the announcement that the American Public Health Association is soon to make a survey of the County Health Department under the Efficiency Bureau of Los Angeles County.

Dr. A. S. Baker, Southern California representative, announces that construction of a health center costing approximately \$100,000 for Belvedere district

will soon be commenced. Dr. Baker is Deputy County Health Officer in charge of Belvedere District.

TRAINING PHYSICIANS IN PUBLIC HEALTH

A course of study to train physicians who are about to enter the field of public health is being given at Nashville, Tenn. This course, conducted under the auspices of the Tennessee State Department of Public Health, and the Department of Preventive Medicine of Vanderbilt University School of Medicine, is primarily for the purpose of changing the attitude of a medical practitioner to that of a health officer. In order to make administrative procedure easier, a faculty committee consisting of Drs. W. S. Leathers, E. L. Bishop, W. K. Sharp and Joseph W. Mountin was formed. Dr. Leathers has charge of the work at the university and the field work is being supervised by Dr. Mountin.

They plan to develop habits of systematic research and study, to review clinical subjects pertaining to public health, to demonstrate field methods and to assign the trainee to definite survey projects in order that his ingenuity and resources can be tested.

NEW HAVEN COUNTY PUBLIC HEALTH ASSOCIATION MEETS

THE regular meeting of the New Haven County Public Health Association was held in New Haven, Conn., March 1, 1928. Some of the papers read were:

"Smallpox: Differential Diagnosis and Other Items of Importance," by Dr. Millard Knowlton, Director, Bureau of Preventable Diseases, State Department of Health; "Some of the Important Findings in the Recent Health Survey in New Haven," by Prof. C-E. A. Winslow, Yale University. and "Public

Health Problems of Villages and Rural Districts," by Willis N. Butrick, Health Officer of Milford and Orange, together with Dr. C. N. Denison, Health Officer of Cheshire; Dr. A. S. McQueen, Health Officer of Branford; Dr. S. P. Taylor, Health Officer of North Haven.

DELTA OMEGA LECTURE

THE Delta Omega Lecture on "The Present Status of School Ventilation" at Massachusetts Institute of Technology, Cambridge, Mass., on March 16, 1928, was given by Thomas J. Duffield, Executive Secretary of the New York Commission on Ventilation.

WAR ON SLEEPING SICKNESS

FOR the purpose of consulting with a number of celebrated European specialists who have made studies of sleeping sickness, Dr. Josephine B. Neal, Director of the Wm. J. Matheson Survey of Epidemic Encephalitis, sailed for Europe recently.

Some of the doctors she intends to visit are: Dr. A. J. Hall, Sheffield, England; Dr. J. R. Perdrau, London, England; Dr. Doerr and Dr. Schnabel, Basle, Switzerland and Dr. G. Levaditi at the Pasteur Institute in Paris.

The Medical Center, 17 East 42nd Street, New York, N. Y. hopes to begin a study of the disease, following Dr. Neal's return from Europe.

AMERICAN CITY TO HAVE HEALTH SECTION

BEGINNING with the April issue the *American City Magazine* is to have a section entitled, "The Month in Public Health." This new feature will consist of an original review of public health progress of particular interest to city officials and civic workers. This department will be conducted by James A. Tobey, Dr. P. H.

PERSONALS

- HELEN CHASE, of Waterbury, Conn., has given \$10,000 to the Waterbury Mental Hygiene Clinic to supplement the work now being done there.
- TREAT B. JOHNSON, Ph.D. has been appointed as Sterling professor of chemistry at Yale University, according to an announcement by the President of Yale. Dr. Johnson has been a member of the Yale faculty since 1898, and is noted for his research on the chemistry of bacteria.
- DR. ALVIN H. CRANZ has been appointed physician to the Connecticut State Prison at Wethersfield, to succeed Dr. Percy B. Battey, recently resigned.
- DR. WILLIAM H. MEYER, formerly resident physician at the Williams Hospital, Lebanon, Ind., has been appointed acting assistant surgeon in the U. S. Public Health Service, assigned to duty at U. S. Marine Hospital Number 2, Boston, Mass.
- DR. JAMES H. STYGALL, Indianapolis, Ind., was elected president of the Indiana State Medical Association, at the annual meeting of the association, held at Gary, February 15-16.
- DR. ELMER C. SINGER was appointed a member of the board of health of Fort Wayne, Ind., to succeed Dr. Raymond J. Berghoff, who resigned.
- DR. HENRY S. HOUGHTON, recently appointed dean of the State University of Iowa College of Medicine, assumed his duties at the University Medical School February 1.
- DR. DANIEL C. STEELSMITH, Sibley, Ia., has been appointed deputy state health commissioner, to succeed Dr. James Wallace, who resigned. Dr. Thomas E. Powers has been appointed to succeed Dr. Steelsmith.
- DR. FRANK B. MALLORY was appointed professor of pathology at the Medical School of Harvard University, on February 1, and Dr. Cornelius P. Rhoads was appointed as instructor in pathology.
- DR. BRUNO S. HARWOOD has resigned from the city health department of New York City, after 24 years' service and Dr. William C. Buntin will take over his office temporarily. A testimonial dinner was given to Dr. Harwood on February 6.
- DR. MARION A. BLANKENHORN and Dr. Roy W. Scott have been promoted from associate professors of medicine to professors at Western Reserve University School of Medicine, Columbus, O.
- DR. FRANCIS E. FRONCZAK, has been reëlected by a unanimous vote, health officer of Buffalo, N. Y., where he has been connected with the health department for 17 years.
- DR. CHARLES A. BENZ, superintendent of laboratories in Buffalo, N. Y. has been appointed director of the division of communicable diseases. He will, however, still have charge of the laboratories.
- DR. E. J. JOHNSTON has been appointed city health officer of South Pasadena, Calif., to succeed Dr. John Robert Reid.
- THE CALIFORNIA STATE BOARD OF PUBLIC HEALTH at its meeting on February 4, appointed the following consultants in epidemiology, animal industry, entomology, sanitary engineering, parasitology, bacteriology, pathology, and legal matters pertaining to the Board: Dr. Walter Brem, Dr. Ernest C. Dickson, Dr. C. M. Haring, Prof. W. B. Herms, Prof. C. G. Hyde, Prof. C. A. Kofoid, J. Macfarland, Dr. Karl E. Meyer and Dr. Wm. Ophuls.

DR. E. F. W. ALEXANDERSON, consulting engineer of the General Electric Company and Radio Corporation of America, was presented with the John Ericsson medal at the 40th anniversary banquet of the American Society of Swedish Engineers in New York, February 11. The award was given Dr. Alexanderson "for his outstanding contributions to the field of radio engineering." The medal, founded in honor of the great scientist and engineer, Captain John Ericsson, has been awarded but once before, in 1926, to Dr. Svante Arrhenius, former head of the Nobel Institute and the first man to advance the theory of ionization.

MARIE T. PHELAN of the Federal Children's Bureau who has been loaned to the Texas State Department of Health to assist with the Birth Registration Campaign has just returned to Austin from a field trip, which included Gregg, Dallas, Tarrant and McLellan counties.

DR. I. R. WHIPPER, colored woman physician of the Children's Bureau of Washington, D. C., has been sent to Texas at the request of Dr. J. C. Anderson, State Health Officer of Texas, to do some work with the midwives of the state. It is hoped that in this way the birth registration work and other state requirements will be greatly improved.

DR. A. J. CROWELL has been elected President of the North Carolina State Board of Health to succeed Dr. J. Howell Way.

DR. JAMES R. SCOTT, City Health Officer of Berkeley, Calif., and formerly County Health Officer of Bernalillo County, N. M., will return to New Mexico April 1 to resume his former duties as Bernalillo County Health Officer at Albuquerque.

DOROTHY R. ANDERSON, Chief, Division of Public Health Nursing, New Mexico Bureau of Public Health, is now giving a short course on Health

Education at the New Mexico State Teachers' College, Silver City.

DR. REUBEN L. KAHN, serologist in the Michigan Department of Health, and a member of the Michigan Public Health Association, has been invited to demonstrate the Kahn test for syphilis before the Serological Conference sponsored by the League of Nations Health Section.

DR. JAMES R. SCOTT formerly with the City Health Department of Berkeley, Calif., has become associated with the County Health Department of Albuquerque, N. M.

DR. NATHAN SINAI, associate professor of public health, University of Michigan, has been granted a year's leave of absence to act as Assistant Director of Study with the Committee on the Cost of Medical Care. Dr. Niles Carpenter, head of the sociology department of the University of Buffalo has also been granted a year's leave of absence to accept a similar position with the committee.

Position Wanted by technician with experience in state health laboratory routine tests. Visitor X Ray short course. Available soon. Address 46 D. M.

The New Type Bacterial Antigen

PNEUMOCOCCUS IMMUNOGEN

FOR THE TREATMENT OF PNEUMONIA

Low in Protein Content

PNEUMOCOCCUS IMMUNOGEN produces less reaction because it contains considerably less protein than a vaccine of corresponding bacterial equivalent. It may be safely used in considerably larger doses than bacterial vaccines.

Pneumococcus Immunogen is offered to the medical profession with the belief that it is an effective type of antigen for use in pneumonia.

The Behavior of Lead in The Animal Organism-I*

ROBERT A. KEHOE, M. D. and FREDERICK THAMANN

Eickberg Laboratory of Physiology, University of Cincinnati, Cincinnati, O.

THE MOST difficult problem in the prevention of industrial lead poisoning arises from the variability in the effect of a given set of conditions upon workmen. The comparatively low toxicity of lead for most men has retarded a general appreciation of the necessity for adequate preventive measures. On the other hand, the remarkable susceptibility to lead of an occasional man has brought about such a state of clinical confusion, that the diagnosis of lead poisoning is often made on the uncertain basis of a history of actual or even presumable exposure to lead compounds. Furthermore, the same individual reacts differently to the same degree of exposure at different times. Thus some individuals apparently develop a degree of immunity to the effects of lead absorption after a period of exposure. The reverse condition—the sudden onset of poisoning in a person of apparently little previous susceptibility—is of more frequent occurrence.

Many attempts have been made to determine the nature of so variable a disease. The collected data illustrate the lack of uniformity in the manifestations of the condition. Animal experimentation has shown that different species of animals, and different individuals of the same species, vary greatly in susceptibility to lead and in the type of induced poisoning which results. There is also great variability in the rate of absorption, and in the rate of excretion in different animals and in the same animal under different conditions.

The foregoing facts indicate that the behavior of lead in the animal organism is subject to a large number of modifying influences. An

* Read before the Industrial Hygiene Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 21, 1927.

understanding of these requires a knowledge of the detailed behavior of lead in the body under a great variety of conditions.

The most fruitful attempt to bring together experimental and clinical data, to investigate them critically, and to discover an underlying mechanism capable of explaining many confusing and apparently conflicting facts, has been made by Aub and his associates.¹ Their presentation of conclusive evidence of the selective localization of lead in the bones, and the passage of lead out of the bones and out of the body under proper conditions, has resulted in important and advantageous therapeutic measures. However, their interpretation of the mechanisms of selective absorption and mobilization of lead in the body does not explain adequately certain clinical and experimental facts. Furthermore, we still require a knowledge as to the nature of the action whereby lead and the other heavy metals cause injury to the living tissues. It becomes necessary, therefore, to investigate further and in greater detail.

Facts presented herein are based on the following selected items of an extensive experimental program: (1) a study of the distribution of lead in a series of rabbits under uniform conditions, in order to determine the limits of variation for one set of conditions; (2) a comparison of the standard type of distribution thus obtained, with the distribution in animals in which lead has been administered differently and which have been given a very much longer time interval after treatment; (3) a study of the excretion of lead in rabbits under normal conditions, a long time after treatment with lead.

EXPERIMENTAL METHODS

1. Preliminary experiments studying the distribution of lead in animals treated with lead compounds showed a considerable variation. Certain gross variations appeared to be explained by some outstanding factor, such as type of lead compound administered, acute infection, parturition, inadequate diet, or the influence of administered acids and salts.² In order to determine a standard type of distribution, a group of 20 full grown rabbits, 10 males and 10 females, were selected because of their similarity in size, age and condition. These were isolated from other animals and from each other in cages in a well lighted, well ventilated room. They were all fed on a standard, mixed diet. Observation was continued 3 weeks to insure against pregnancy in the females and illness in any member of the group. Each animal was given 50 mg. of lead per week in one dose as a solution of lead chloride, for 4 weeks, by means of a stomach tube.

Ten animals developed respiratory infections, varying from slight snuffles to pneumonia, during a period of extreme changes in the weather. The remainder remained well during the entire period. Four of the sick animals died, the other 6 showed some evidence of low grade infection up to the conclusion of the experiment, and at necropsy. These were all localized head infections, without evidence of systemic intoxication.

After the fourth dose an interval of 2 weeks was allowed in order that the alimentary tract might free itself of unabsorbed administered lead. Then, under light anesthesia the blood was drawn off from the heart, slowly and steadily by means of a syringe, until death resulted. This permitted the obtaining of a large quantity of blood for analysis and in addition freed the tissues largely of their blood. The skin was removed with great care not to contaminate the underlying tissues, and discarded. The other tissues were separated cleanly as follows: bone, liver, kidneys, central nervous system (brain and spinal cord), spleen, muscle, adipose tissue, and intestinal tract (washed free of its contents). In the case of several animals the hair on the sides and back which was least likely to be contaminated at any time with feces or urine, was clipped off for separate analysis.

2. In order to determine whether the method of administration and time alter relative distribution of lead in the tissues a number of rabbits which had been given lead, but which had received none for months, were killed and their tissues were examined similarly. All of these had been given lead intravenously. No other recognizable factor was present, except time, however, for great care was used to include only such animals as were perfectly healthy, and which had received no treatment of any kind beyond the administration of water soluble salts of lead.

3. A large series of rabbits has been studied with reference to the excretion of lead under a variety of natural and experimentally induced conditions. The rate of excretion is found to vary strikingly with some of these conditions. The same factors which apparently modify the distribution of lead in the tissues, also alter the rate of excretion.⁷ There is, in addition, a striking variation from day to day, dependent upon the amount of food eaten, the amount of water consumed, and the actual amount of excreta. Therefore, it is most important in a study of excretion under normal conditions, not to use animals which are ill in any way, or which have been exposed to any of the recognizable influences which change the distribution of lead in their tissues. It is equally necessary to collect the excreta over a period of time sufficient to equalize the daily variation. Four immediately successive periods of 4 full days each were chosen for this purpose. The average daily excretion was calculated on this basis. Great caution had to be used also in preventing contamination of the excreta with lead from sources other than that intended. Thirteen rabbits carefully selected in this way have supplied the data for this item of the study. They were killed for analysis at the conclusion of the last period over which their excretions were collected. No pathological abnormality was found in any of these at necropsy.

DATA AND DISCUSSION

Table I shows all the analytical data obtained from the group of rabbits treated in the standard manner. A careful examination of the analytical method in use at the time of these analyses has shown an inconstant but possible experimental error of ± 0.03 mg. of lead. This error has recently been eliminated by a slight modification of technic, but such quantities may not be considered as certainly significant in these data. Therefore, no calculations or conclusions are based on them. All other quantities are used as the basis for the calculation of the concentration of lead in the particular organ. In order to com-

pare the distribution of lead where the total lead content of the animal varies, calculation has been made of what may be called an "index of selective absorption." This is recorded as the ratio existing between the concentration of lead in the entire carcass, exclusive of the skin, in milligrams per cent, and the concentration of lead in a tissue in milligrams per cent.

Table II illustrates the distribution in these animals with reference to the indices of selective absorption only. The results which are in doubt because of their smallness, as considered against the possible experimental error, are marked "nil?" The infected animals are separated from the others in the table because of the possible influence of their illness on distribution. However, there is no appreciable effect of this factor on the results so that they are included in the calculation of the mean values of the absorption "index." It is not possible to calculate these values for all the tissues concerned both because of the doubtful character of the low results and also because of their variability. In the case of the liver, bone, fat and muscle, however, these values may be calculated with assurance as to the accuracy of the analytical results. The calculated mean and the standard deviation from it are indicated in the table.

A number of significant things are seen in the tabulated data. First of all the quantities of lead found in the entire animals (from 1 to 3 mg.) represent only a very small fraction of the lead administered. There is reason to believe that the method of disposing of the organic material of the tissues (ashing in an electric furnace at a temperature carefully controlled so as not to exceed 500° C.) brings about a slight loss of the lead by volatilization.⁴ (This fact probably indicates the formation of compounds of the lead with organic constituents of the tissues.) This loss is never more than a small fraction of the lead present, however, so that it may not be considered as of significance to the present matter. The low lead content of these animals is due to incomplete absorption of the administered lead, or to rapid elimination of that absorbed, or to a combination of both. Examination of data bearing on these two points indicates the probability that not more than 10 per cent of the administered lead was absorbed into the tissues, and that continuous excretion has accounted for the loss of from 50 to 80 per cent of that absorbed.⁵

Although the blood uniformly contains little or no lead, the liver, the adipose tissue, and the muscles, in addition to the bones, contain significant quantities. There is, therefore, an unquestionable selective affinity for lead on the part of all of these tissues. This may or may not be due to some common factor in their physical or chemical char-

acter. In either case their lead binding power differs quantitatively. Other tissues in the body may have similar affinities for lead. Thus an organ may be so small that its lead content is not capable of accurate determination; or its location along the circulatory system, with reference to the portal of entry may be such as to diminish its opportunity

for contact with the blood at a time when it contains high concentrations of lead. This latter factor may be tested by comparing the distribution of lead in the tissues of animals which have received lead in different ways.

Thus Tables III and IV show the effect of intravenous administration of lead upon its distribution in a series of animals. A very long time has elapsed since the administration, during which a very large proportion of the lead has been lost from the body. Yet two things are discernible. There is an increased frequency in the occurrence of significant quantities of lead in tissues other than the bones, liver, adipose tissue and muscle, without corresponding concentrations of lead in the circulating blood. The concentrations in certain tissues may be of a magnitude comparable with that of the bone. This is especially true of the kidneys and the central nervous system. There is a strong probability, therefore, that these tissues have a considerable affinity or combining power for lead, if they have an opportunity to come in contact with adequate concentrations brought by the circulating blood. There is little doubt that the chances of such an occurrence are very much greater if lead is administered intravenously, rather than by way of the alimentary tract. In the latter case, there is ample reason to believe that the liver is normally capable of preventing the appearance of high concentrations of lead in the blood.

The question naturally arises as to whether the lead is bound in all these tissues in the same manner, or whether it may not be firmly bound or stored in inert form in some, while being in less stable combinations in others. It is quite suggestive, in this connection, that despite the loss of 90 per cent or more of their total lead, the relative distribution of lead in the bones, liver, adipose tissue and muscle remains essentially unchanged. Undoubtedly the greatest quantity of the lead lost from the body was removed from the bones. There are three ways in which the relative distribution can remain thus constant. The lead may have been lost rapidly from certain organs with

little relative affinity for it, and subsequently replaced by lead which was released from others in some intermittent normal or accidental manner; or all the tissues may have given up their lead at a rate varying only with the differences in their lead concentrations; or the process of elimination may have been intermittent for all of the tissues, as a result of some naturally or accidentally occurring condition,

TABLE V
RELATION OF EXCRETION TO QUANTITY IN BODY

Rabbit Number	Lead Administered			Intervening time in months	Average Daily Excretion Mgs.	Lead in Carcass Mgs.	Excretion Mgs. Daily/ Mgs. in Body
	Manner	Doses	Amount Mgs.

199	0	4	600	6	0.165	6.07	0.027
200	0	4	600	6	0.160	13.61	0.012

capable of simultaneous modification of all the mechanisms whereby lead is held in the tissues.

In any case, it is plain that in the case of rabbits, under apparently normal conditions, lead is capable of steady excretion from all the tissues on which these data supply information. (Other data demonstrate a remarkable ability of central nervous system to retain lead, almost quantitatively.^o)

The same point is illustrated by the data in Table V. Here excretion of lead, under normal conditions shows a strikingly frequent dependence upon the total lead content of the animal. Considering individual variation, and the probabilities for the existence of unrecognized factors in the underlying processes of lead mobilization and excretion, there is a notable degree of uniformity. Therefore, one may conclude that the rate of lead excretion varies generally with the quantity of lead in the entire body. It is difficult to understand in any other way the uniformly small proportion of the administered lead remaining in these animals. The loss of from 10 to almost 80 mg. of lead in 6 or 8 months cannot be explained on the basis of the rate of excretion found at the time of these observations. Lead must have been poured out at a much more rapid rate in the periods following shortly after administration. If the truth of this reasoning be accepted, then the lead in all of the tissues is influenced by the same set of reactions in the body, or by varying reactions in different tissues operating simultaneously or in close succession.

These considerations lead to the belief that lead is not converted quantitatively in the body to the relatively insoluble inorganic secondary and tertiary phosphates.¹⁻³ Speculation as to a mechanism capable of explaining the experimental facts suggest that a significant portion of the lead in the body exists in the form of compounds or complexes with organic constituents of the tissues. To the extent to which inorganic tertiary and secondary phosphates are present, an equilibrium may exist between them and such organic compounds—an equilibrium constantly shifting by reason of the conversion of the organic compounds into the forms in which lead is excreted.

PRACTICAL APPLICATIONS

The application of the observed facts to clinical and industrial practice may be briefly suggested. Data obtained on a large number of cases of lead absorption in man, give evidence that both fecal and urinary lead excretion in man vary in quantity with the extent and severity of exposure to lead compounds.⁴ This provides indirect evidence that the quantitative factor in such excretion is based upon the quantity of lead in the body of the subject. It also indicates a probability that the conditions which influence the absorption and excretion of lead in the normal man are similar to those in the rabbit. Direct evidence in this matter will be difficult if not impossible to obtain. If such tentative conclusions are correct, however, it should be possible to determine the approximate lead content of a given subject by a careful study of his lead excretion over a sufficient period of time, during which no known factor is allowed to modify the normal rate. It may also be possible to determine the relationship of a given rate of excretion of lead to the appearance of symptoms.

Furthermore, if lead excretion varies with exposure, it becomes possible by studying a sufficient number of men in this way to measure adequately the lead hazards associated with various occupations. Such a method provides a check on the adequacy of all the preventive measures used to control a given hazard, including the extremely variable and undependable element of carefulness on the part of the workers. The usefulness of such information, capable of interpretation on a sound basis, is obvious, both in the domain of industrial preventive medicine, and in the larger field of the public health.

Accuracy of Certified Causes of Death*

SINCE our report of a year ago before this section, your Committee on Accuracy of Certified Causes of Death has had several meetings and two members of the committee have, at the request of the League of Nations, represented American opinion in this field at a conference of statistical experts in Geneva, and have presented formally to the special committee of the International Institute of Statistics, their point of view prior to the conference held in Paris, in April, 1927.

The Health Section of the League of Nations assembled a small group of medical registrars, statistical officers and physicians, to consider preliminary revision of the International List. The result of this conference was the preparation of an intermediate list of 90 titles, as well as the revision of the abridged list to include only 27 titles. These lists were published in the September issue of the *American Journal of Public Health*.

At the meeting of the Committee of the International Institute of Statistics in Paris, consideration of the revision of the International Lists was continued in much the same spirit, and by several of the same persons who attended the Geneva conference, with the result that three revised lists have been prepared for presentation at the meeting of the International Institute at Cairo in December of this year. These lists also have been published in the September *American Journal of Public Health*.

Your committee is of the opinion that the issuance of three international lists is desirable; a detailed list of approximately 200 titles; an intermediate list of approximately 90 titles; and an abridged list of something over 30 titles.

Since the two meetings in Europe above referred to, your committee has again considered all the facts at hand, and in its present report offers you three lists which are designed to preserve comparability, and recommends your approval of them as the expression of American opinion, to be forwarded to both the Health Section of the League of Nations and the International Institute of Statistics, in response to their formal requests.

Other countries have in preparation similar revisions, and it is expected that further conferences under international and scientific

* Report of the Committee on the Accuracy of Certified Causes of Death and Its relation to Mortality Statistics and the International Classification. (Adopted by the Vital Statistics Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.)

auspices will be held between now and 1929, when the French Government will convoke the International Conference in Paris which will decide the final revision of the International Lists as of the year 1930.

All these preliminary conferences are, in the opinion of your committee, desirable and necessary for the purpose of reaching the greatest possible agreement as to principles and practices before the final conference of 1929. It is the opinion of your committee that very considerable improvement has been attained in the terms used, in the groups under which the terms are assembled, and in the addition of an intermediate list to the detailed and abridged lists of causes of death already in use.

In the preparation of the three revised lists as offered for your consideration, the factors of greatest importance (after scientific accuracy in terminology) in determining acceptance or rejection of suggestions for changes, coming from other countries, or originating from American statisticians, have been the preservation of comparability with past records, and the facilitating of a wider use of the International List than has been obtained up to the present time.

The committee voted to include as a part of its own report that of the committee on Joint Causes of Death. This appeared in the February, 1928, issue of the *American Journal of Public Health* and *The Nation's Health*, and need not be repeated here.

The following are the lists recommended by your committee. The numbers in parentheses in the Intermediate and Abridged lists refer to the titles of the Detailed list which are included.

REVISED LISTS

A. DETAILED LIST

- | | |
|-------------------------------------|--|
| 1. Typhoid and paratyphoid fever | 12. Cholera nostras |
| (a) Typhoid fever | 13. Dysentery |
| (b) Paratyphoid fever | (a) Amebic |
| 2. Typhus fever | (b) Bacillary |
| 3. Malta fever | (c) Unspecified or due to other causes |
| 4. Small-pox | 14. Plague |
| 5. Measles | (a) bubonic |
| 6. Scarlet fever | (b) pneumonic |
| 7. Whooping cough | (c) septicemic |
| 8. Diphtheria | (d) unspecified |
| 9. Influenza | 15. Erysipelas |
| (a) with pulmonary complications | 16. Acute anterior poliomyelitis |
| (b) without pulmonary complications | 17. Lethargic encephalitis |
| 10. Mumps | 18. Meningococcus meningitis |
| 11. Asiatic cholera | 19. Glanders |

24. Tuberculosis of the meninges and central nervous system
25. Tuberculosis of the intestines and peritoneum
26. Tuberculosis of the vertebral column
27. Tuberculosis of the bones and joints (vertebral column excepted)
 - (a) bones
 - (b) joints
28. Tuberculosis of other organs
 - (a) Tuberculosis of the skin and subcutaneous tissue
 - (b) Tuberculosis of the lymphatic system (mesenteric and retroperitoneal glands excepted)
 - (c) Tuberculosis of the genitourinary system
 - (d) Tuberculosis of organs other than above
29. Disseminated tuberculosis
 - (a) Acute
 - (b) Chronic or unspecified
30. Leprosy
31. Syphilis
 - (a) Congenital
 - (b) Acquired
 - (c) Unspecified
32. Gonococcus infection
33. Purulent infection, septicemia (including pyemia and bacteriemia).
34. Malaria
 - (a) Malarial fever
 - (b) Malarial cachexia
35. Relapsing fever (spirillum obermeieri)
36. Yellow fever
37. Spirochetal hemorrhagic jaundice
38. Other spirochetoses
39. Ancylostomiasis
40. Hydatid cyst
 - (a) of the liver
 - (b) of other organs or tissue
41. Other diseases due to animal parasites
42. Mycoses
43. Other epidemic, endemic, infectious, and parasitic diseases*
*Diseases of unusual prevalence should be separately tabulated.
44. Cancer and other malignant tumors of the buccal cavity
45. Cancer and other malignant tumors of the pharynx, esophagus, stomach, liver
46. Cancer and other malignant tumors of the peritoneum, intestines, rectum
47. Cancer and other malignant tumors of the female genital organs
48. Cancer and other malignant tumors of the breast
49. Cancer and other malignant tumors of the skin
50. Cancer and other malignant tumors of other or unspecified organs
51. Benign tumors and tumors not returned as malignant (without exception)*
*Subdivide by at least ten subtitles by anatomical site.
52. Acute rheumatic fever
53. Chronic rheumatism, osteoarthritis, gout
 - (a) Gout
 - (b) Others under this title
54. Scurvy
55. Pellagra
56. Beriberi
57. Rickets and other softenings of the bones
 - (a) Rickets
 - (b) Other softenings of the bones
58. Diabetes mellitus
59. Anemia, pernicious and other
 - (a) Pernicious anemia
 - (b) Other anemias and chlorosis
60. Leukemia and Hodgkin's disease
 - (a) Leukemia
 - (b) Hodgkin's disease
61. Diseases of the pituitary gland
62. Diseases of the thyroid gland
 - (a) Exophthalmic goiter
 - (b) Other diseases of the thyroid gland
63. Diseases of the parathyroid glands
64. Diseases of the thymus gland
65. Diseases of the adrenal glands or capsules (Addison's disease)
66. Diseases of the spleen
67. Alcoholism (acute or chronic)*
*Acute poisoning by methyl or denatured alcohol excluded; see 180
68. Chronic lead poisoning
69. Other chronic occupational poisonings
70. Other chronic poisonings
71. Other general diseases
72. Encephalitis
73. Meningitis
74. Tabes dorsalis (locomotor ataxia)
75. Other diseases of the spinal cord
76. Cerebral hemorrhage, apoplexy
 - (a) Cerebral hemorrhage
 - (b) Cerebral embolism and thrombosis
77. Paralysis without specified cause
 - (a) Hemiplegia
 - (b) Others under this title
78. General paralysis of the insane
79. Other forms of mental alienation
80. Epilepsy
81. Convulsions (nonpuerperal; 5 years and over)
82. Infantile convulsions (under 5 years of age)
83. Chorea
84. Neuralgia and neuritis
85. Other diseases of the nervous system
 - (a) Softening of the brain

- (b) Other diseases of the nervous system
- 86. Diseases of the eye and annexe
- 87. Diseases of the ear and of the mastoid process
 - (a) Diseases of the ear
 - (b) Diseases of the mastoid
- 88. Pericarditis
 - (a) Acute and unspecified
 - (h) Chronic
- 89. Endocarditis and myocarditis (acute)
- 90. Chronic endocarditis and valvular diseases of the heart
- 91. Angina pectoris
- 92. Other and unspecified diseases of the heart
 - (a) Chronic myocarditis
 - (b) Functional diseases of the heart
 - (c) Other and unspecified diseases of the heart
- 93. Aneurysm
- 94. Arteriosclerosis and other diseases of the arteries
 - (a) Arteriosclerosis
 - (b) Other diseases of the arteries
- 95. Embolism and thrombosis (cerebral and pulmonary excepted)
- 96. Diseases of the veins (varices, hemorrhoids, phlebitis, etc.)
- 97. Diseases of the lymphatic system, (lymphangitis, etc.)
- 98. Hemorrhage without specified cause
- 99. Other diseases of the circulatory system
- 100. Diseases of the nasal fossae and their annexe
- 101. Diseases of the larynx
- 102. Bronchitis
 - (a) acute
 - (h) chronic
 - (c) unspecified (under 5 years of age)
 - (d) unspecified (5 years and over)
- 103. Bronchopneumonia (includes capillary bronchitis)
- 104. Pneumonia, lobar and unspecified
 - (a) lobar
 - (h) unspecified
- 105. Pleurisy
- 106. Congestion, embolism, and hemorrhagic infarct of the lung
- 107. Gangrene of the lung
- 108. Asthma
- 109. Pulmonary emphysema
- 110. Other diseases of the respiratory system (tuberculosis excepted)
 - (a) Chronic interstitial pneumonia, including occupational diseases of the respiratory system
 - (b) Diseases of the mediastinum
 - (c) Others under this title
- 111. Diseases of the mouth and annexe
- 112. Diseases of the pharynx and tonsils (including adenoid vegetations)
- 113. Diseases of the esophagus
- 114. Ulcer of the stomach and duodenum
 - (a) Ulcer of the stomach
 - (b) Ulcer of the duodenum
- 115. Other diseases of the stomach (cancer excepted)
- 116. Diarrhea and enteritis (under 2 years of age)
- 117. Diarrhea and enteritis (2 years and over)
- 118. Appendicitis and typhlitis
- 119. Hernia, intestinal obstruction
 - (a) Hernia
 - (b) Intestinal obstruction
- 120. Other diseases of the intestines
- 121. Cirrhosis of the liver
 - (a) Specified as alcoholic
 - (h) Not specified as alcoholic
- 122. Biliary calculi
- 123. Other diseases of the liver and biliary passages (includes acute yellow atrophy)
- 124. Diseases of the pancreas
- 125. Peritonitis without specified cause
- 126. Other diseases of the digestive system (cancer and tuberculosis excepted)
- 127. Acute nephritis (including unspecified under 10 years of age)
- 128. Chronic nephritis (including unspecified 10 years and over)
- 129. Other diseases of the kidneys and annexe
- 130. Calculi of the urinary passages
- 131. Diseases of the bladder
- 132. Diseases of the urethra, urinary abscess, etc.
 - (a) Stricture of the urethra
 - (h) Others under this title
- 133. Diseases of the prostate
- 134. Nonvenereal diseases of the male genital organs
- 135. Salpingitis and pelvic abscess (female)
- 136. Nonpuerperal uterine hemorrhage
- 137. Other diseases of the female genital organs
- 138. Nonpuerperal diseases of the breast (cancer excepted)
- 139. Accidents of pregnancy
 - (a) Abortion
 - (h) Ectopic gestation
 - (c) Others under this title
- 140. Puerperal hemorrhage
- 141. Other accidents of labor
 - (a) Cesarean section
 - (h) Other surgical and instrumental deliveries
 - (c) Others under this title
- 142. Puerperal septicemia
- 143. Puerperal phlegmasia, embolism, sudden death
- 144. Puerperal albuminuria, eclampsia, and convulsions

145. Other conditions of the puerperal state
146. Gangrene
 - (a) Senile
 - (b) Others
147. Furuncle
148. Acute abscess
149. Other diseases of the skin and annexa
150. Diseases of the bones (tuberculosis excepted)
151. Diseases of the joints (tuberculosis and rheumatism excepted)
152. Other diseases of the organs of locomotion
153. Congenital malformations (stillbirths not included)
154. Congenital debility, icterus, and sclerema
155. Premature birth; Injury at birth
 - (a) Premature birth
 - (b) Injury at birth
156. Other diseases peculiar to early infancy
157. Lack of care
158. Senility
159. Suicide by solid or liquid poisons (corrosive substances excepted)
160. Suicide by corrosive substances
161. Suicide by poisonous gas
162. Suicide by hanging or strangulation
163. Suicide by drowning
164. Suicide by firearms
165. Suicide by cutting or piercing instruments
166. Suicide by jumping from high places
167. Suicide by crushing
168. Other suicides
169. Infanticide (murders under 1 year)
170. Homicide by firearms
171. Homicide by cutting or piercing instruments
172. Other homicides

NOTE: In classifying deaths from accidents, the primary nature of the accident takes preference over the mode of death. For example, a death resulting from a fracture of skull sustained in an automobile accident, would be charged to the latter.

173. Accidents in mines and quarries
174. Accidents from machinery
175. Accidents from transportation
 - (a) Railroads
 - (b) Street cars
 - (c) Automobiles
 - (d) Motorcycles
 - (e) Aeroplanes and balloons
 - (f) Water transportation
 - (g) Other vehicles
176. Conflagration
177. Accidental burns (conflagration excepted)
178. Poisoning by food
179. Poisoning by venomous animals
180. Other acute accidental poisonings (gas excepted)

181. Accidental absorption of irrespirable, irritating, or poisonous gas
182. Accidental mechanical suffocation
183. Accidental drowning
184. Accidental traumatism by firearms
185. Accidental traumatism by cutting or piercing instruments
186. Accidental traumatism by fall
187. Injuries by animals (not poisoning)
188. Starvation (deprivation of food or water)
189. Excessive cold
190. Excessive heat
191. Lightning
192. Other accidental electric shocks
193. Other external violence
194. Sudden death
195. Cause of death not specified or ill-defined

B. INTERMEDIATE LIST

1. Typhoid and paratyphoid fever (1)
 2. Small-pox (4)
 3. Measles (5)
 4. Scarlet fever (6)
 5. Whooping cough (7)
 6. Diphtheria (8)
 7. Influenza (9)
 8. Dysentery (13)
 9. Tuberculosis of the respiratory system (23)
 10. Tuberculosis, other forms (24-29)
 11. Syphilis (31)
 12. Purulent infection, septicemia (including pyemia and bacteriemia (33)
 13. Malaria (34)
 14. Diseases due to animal parasites (39, 40, 41)
 15. Other epidemic, endemic, infectious and parasitic diseases (2, 3, 10, 11, 12, 14-22, 30, 32, 35-38, 42, 43)
 16. Cancer and other malignant tumors (44-50)
 17. Benign tumors and tumors not specified as malignant (without exception) (51)
 18. Acute rheumatic fever (52)
 19. Chronic rheumatism, osteoarthritis, gout (53)
 20. Avitaminoses (deficiency diseases) (54-57)
 21. Diabetes mellitus (58)
 22. Pernicious and other anemias (59)
 23. Leukemia and Hodgkin's disease (60)
 24. Diseases of the thyroid gland (62)
 25. Other diseases of nutrition and of the ductless glands (61, 63, 64, 65, 66)
 26. Alcoholism (acute or chronic) (67)
- NOTE: Does not include acute poisoning by methyl or denatured alcohol. See Title No. 84.
27. Other chronic poisonings (68-70)
 28. Other general diseases (71)
 29. Meningitis (73)

30. Tabes dorsalis (locomotor ataxia) (74)
31. Cerebral hemorrhage, apoplexy (to include paralysis, hemiplegia, cerebral embolism and thrombosis) (76, 77)
32. General paralysis of the insane (78)
33. Other forms of mental alienation (79)
34. Epilepsy (80)
35. Other diseases of the nervous system (72, 75, 81-85)
36. Diseases of the eye, the ear and their annexa (86, 87)
37. Pericarditis (88)
38. Endocarditis and myocarditis (acute) (89)
39. Chronic endocarditis and valvular diseases of the heart (90)
40. Angina pectoris (91)
41. Other and unspecified diseases of the heart (92)
42. Aneurysm (93)
43. Other diseases of the arteries (94)
44. Embolism and thrombosis (cerebral and pulmonary excepted) (95)
45. Other diseases of the circulatory system (96-99)
46. Bronchitis (102)
47. Bronchopneumonia (includes capillary bronchitis) (103)
48. Pneumonia, lobar and unspecified (104)
49. Pleurisy (105)
50. Other diseases of the respiratory system (tuberculosis excepted) (100, 101, 106-110)
51. Ulcer of the stomach and duodenum (114)
52. Diarrhea and enteritis (116, 117)
53. Appendicitis and typhlitis (118)
54. Hernia, intestinal obstruction (119)
55. Cirrhosis of the liver (121)
56. Biliary calculi (122)
57. Other diseases of the liver and biliary passages (includes acute yellow atrophy) (123)
58. Other diseases of the digestive system (111-113, 115, 120, 124-126)
59. Acute nephritis (127)
60. Chronic nephritis (128)
61. Other diseases of the kidneys and annexa (129)
62. Calculi of the urinary passages (130)
63. Diseases of the bladder (131)
64. Diseases of the prostate (133)
65. Other nonvenereal diseases of the genito-urinary system (132, 134-138)
66. Accidents of pregnancy (139)
67. Puerperal hemorrhage (140)
68. Puerperal septicemia (142)
69. Puerperal albuminuria, eclampsia, and convulsions (144)
70. Other puerperal causes (141, 143, 145)
71. Diseases of the skin and cellular tissue (146-149)
72. Diseases of the bones and of the organs of locomotion (tuberculosis and rheumatism excepted) (150-152)
73. Congenital malformations (stillbirths not included) (153)
74. Congenital debility, icterus and sclerema (154)
75. Premature birth; Injury at birth (155)
76. Other diseases peculiar to early infancy (156, 157)
77. Senility (158)
78. Suicide (159-168)
79. Homicide (169-172)
80. Accidents in mines and quarries (173)
81. Accidents from machinery (174)
82. Accidents from transportation (175)
83. Accidental burns (including conflagrations) (176, 177)
84. Acute accidental poisonings (gas excepted) (178-180)
85. Accidental absorption of irrespirable, irritating, or poisonous gas (181)
86. Accidental drowning (183)
87. Accidental traumatism by fall (186)
88. Other external violence (182, 184, 185, 187-193)
89. Cause of death not specified or ill-defined (194, 195)

C. ABRIDGED LIST

1. Typhoid and paratyphoid fever (1)
2. Small-pox (4)
3. Measles (5)
4. Scarlet fever (6)
5. Whooping cough (7)
6. Diphtheria (8)
7. Influenza (9)
8. Tuberculosis of the respiratory system (23)
9. Tuberculosis, other forms (24-29)
10. Cancer and other malignant tumors (44-50)
11. Benign tumors and tumors not returned as malignant (without exception) (51)
12. Diabetes mellitus (58)
13. Cerebral hemorrhage, apoplexy (to include paralysis, hemiplegia, cerebral embolism and thrombosis) (76, 77)
14. Diseases of the heart (88-92)
15. Other diseases of the circulatory system (93-99)
16. Bronchitis (102)
17. Pneumonia (all forms) (103, 104)
18. Other diseases of the respiratory system (100, 101, 105-110)
19. Diarrhea and enteritis (116, 117)
20. Appendicitis and typhlitis (118)
21. Cirrhosis of the liver (121)

22. Other diseases of the digestive system (111-115, 119, 120, 122-126)
23. Acute and chronic nephritis (127, 128)
24. Other diseases of the genitourinary system (129-138)
25. Puerperal septicemia (142)
26. Other puerperal causes (139-141, 143-145)
27. Congenital debility, malformations, premature birth, etc. (153-157)
28. Other defined diseases (2, 3, 10-22, 30-43, 52-57, 59-75, 78-87, 146-152, 158)
29. Suicide (159-168)
30. Violent deaths (suicide excepted) (169-193)
31. Cause of death not specified or ill-defined (194, 195)

Stop! Look For The Approved Service Station

IN Delaware the State Board of Health and the owners of service stations have combined efforts to safeguard the health of motorists across the state and to afford them sanitary conveniences.

Along the roads signs posting the service stations have been erected indicating that a couple of hundred feet ahead pure water supplies and sanitary toilets are available.

Periodic monthly inspection of all signed service stations is made by the State Board of Health and where sanitary standards demanded by health authorities are not maintained, the signs are taken down. Sixteen stations are equipped with water under pressure and have flush toilets with connection to septic tanks. The majority provide wash basins, soap and paper towels and cups. Two of the approved stations have shower baths. Several provide rest rooms for women.

The signs erected, at an original cost of \$6.30 each, by the service stations are 32" on each face with a green back-

ground, white letters and a white border. They are mounted on green posts 9' x 5" x 3". The sign bears a Blue Hen, the insignia of the State of Delaware.

The Venereal Disease Clinic*

A. J. CASSELMAN, M. D., DR. P. H.

Consultant, Bureau of Venereal Disease Control, New Jersey State Department of Health, Trenton, N. J.

THE essentials in the organization and operation of a venereal disease clinic will vary according to the amount of money available and the purpose of the clinic.

In this paper the essentials of only one type of clinic will be considered, the clinic which is run chiefly in the interest of public health in a city with a population of not less than 25,000 or in a smaller center serving a population of at least 50,000. In cities of half a million or more inhabitants, certain clinics may have an overabundance of funds and may find it necessary to add to the essentials in order to increase the budget, but some of the worst clinics may be found in the largest cities. In any city, the essentials described will serve as a framework, and additions may be made according to the available financial and medical facilities, and the necessity of treating a greater number of persons.

ESSENTIALS OF ORGANIZATION AND OPERATION

Organization—The physician who is organizing a clinic should get the active support of the local and state health departments as well as the hospital or branch of the local government which provides the clinic facilities. The physician alone may have difficulty in educating the local politicians to the necessity for a clinic, but the educational work by the local and state health department will teach the local officials the need for a venereal disease clinic.

If the clinic is to be placed in a small hospital in a small town there may be some difficulty in getting clinic space, although in the larger city the hospital usually has run a clinic long before the department of health became interested. Before the war many of these hospital clinics were of doubtful value to the community, but the need for efficient antivenereal work during the war stimulated these clinics to do more scientific work, and local health departments since then have succeeded in making many of them of greater value to the community by stimu-

* Read at a Special Session on Venereal Disease Control, of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

lating a public health attitude. The local health department should be active in supervising and often in performing the public health work of the clinic. The best results are obtained where an active health officer actually controls the work of the clinic and directs its public health activities.

In many places where there were no clinics the state health departments have provided funds for the first year while the clinics were being organized, but it should be realized that every clinic is primarily a local problem and should be supported by those it serves. Usually there is little difficulty in obtaining the necessary funds in localities really needing clinics. Most hospitals are willing to supply space if the local health department supplies the drugs. In fact, many hospitals bear the entire burden, except for the assistance of a small fee from the patient.

When the clinic is entirely supported by the hospital, usually the physicians receive no remuneration other than the experience they may get and the advertising value of the position. In some hospitals, a fee is charged and the physician is given money for his services. The objection to this plan is that there usually is active competition by the pay clinic with many practicing physicians even though a pay clinic does not injure the practice of those who treat only the wealthy.

In the hospital clinic, a nurse is supplied for the clinic hours, but sometimes there is difficulty in obtaining a clerk, so occasionally the nurse is given this additional work. When a clerk is not provided, usually there is no follow-up work done, unless it is by the local health department. Efficient follow-up work is the essential public health work of the clinic, as it brings under treatment sources of infection and keeps the fresh cases under treatment until they remain permanently non-infectious. A clinic without efficient follow-up service is of doubtful value to the community.

In the public health clinic, run and financed by the local health department, the physician usually is paid a yearly salary. This salary varies from a nominal figure to adequate compensation, as each community has a different idea about the public health value of physicians.

The probable reason for the extreme variations in methods of financing clinics is that venereal disease clinics have only recently become of value to public health. Previously clinics were merely places where physicians acquired experience in examining patients instead of, as now, being places where the patients are relieved and made of little danger to the public health.

Operation—For the operation of the clinic, the essential staff consists of a physician, a nurse, and a clerk who is also the follow-up worker. Usually there will be a much needed assistant physician.

The physician should assign the duties of the staff, form the policies of the clinic, and teach the others to do much of the examination and treatment work and do the rest himself.

The nurse should prepare the clinic, the drugs, and instruments for use at each clinic period. The nurse usually is a woman and may prepare the patients of both sexes. She should be held responsible for all equipment being in the proper condition before it is to be used. If the nurse is incompletely trained, the physician should see that she learns to keep the needles polished with a scouring powder and sharpened with a fine pocket stone and free from any hooks or burrs. Syringes of good quality can be dropped into boiling water and sterilized ready for use with needles attached, so there is no necessity for separate sterilization and mixing of plungers and barrels with greater chance for contamination in the assembling process. She should teach the patients to get into position for examination or treatment quickly. After a little training, an intelligent nurse or other person can take blood specimens, and give intramuscular and intravenous injections, under the supervision of a physician. If the physician does most of this work, the nurse should fill the syringes, and receive the intravenous syringes as they are used, immediately running water through the syringes and needles and returning them to the sterilizer.

The clerk should admit the patients to the clinic, fill in the histories as far as possible, check the delinquent patients and send out the form letters requesting them to return. The clerk may do the follow-up work of delinquent patients if it is not done by the local health department or the nurse.

Follow-up work can be done not only by outside visits and letters, but by the patients themselves. The patient in most cases can be persuaded by means of proper educational work in the clinic to bring in the known source of infection. This educational work by all the members of the staff will put the patients in such a frame of mind as will decrease the number of delinquent patients. There will be a certain amount of overlapping of duties, but the physician can decide on the basis of local conditions the best way to assign the work.

The operation of the clinic will be much simplified if there is a definite routine for each patient on admission.

An intelligent clerk with a little experience can classify correctly with a provisional diagnosis of gonorrhea or syphilis most of the patients as they apply for treatment. This clerk should fill in the history with the name, address, date, age, sex, color, nativity and marital status, the apparent duration of infection, the name and address of the source of infection, the date of exposure as nearly as can be deter-

mined, the date of the first symptoms, and sometimes naming the important symptoms with a very short statement of the subsequent course of the disease. The patient's occupation should be entered, together with the weekly income and the number of dependents, the employer's name and business address, and the name and address of any persons exposed since infection.

If the patient has congenital syphilis, the name and address of the father and mother and sisters and brothers should be listed, and the patient should be urged to bring these persons into the clinic for examination. If the patient has acquired syphilis, the name of the husband or wife and children should be entered and the patient should be told to bring in these exposed persons for examination. In states where it is required by law, the name and address of the source of infection should be reported to the state department of health, and an entry should be made on the history as a check to show that a report was sent to the state department of health. Sometimes these reports cannot be sent out immediately and there should be some way of checking over the histories from time to time.

If the patient has gonorrhea all persons exposed since the time of the infecting contact should be placed under observation by a visit to the clinic. Their names should be entered on the history form immediately, and the findings when they are brought in and examined.

After the clerk has filled in the history as fully as possible, the patient is taken to the physician to have the examination completed, the diagnosis made, any necessary treatment outlined provisionally on the history, and any further recommendations made about contacts and diagnostic procedures. If it is possible before any treatment is given, the social worker or some other person should make the patient thoroughly understand his duty in avoiding any further spreading of his disease and the assistance he should render in helping to control venereal disease as a partial return for the medical service he is to receive. A card for the immediate attention of the follow-up worker should be made out for each source of infection or apparently infectious contact.

The follow-up worker should inspect the treatment sheets at definite intervals to see that the patients are attending the clinic regularly. The physician should mark on the chart by drawing a line for each week the patient is told he need not attend the clinic whenever his injections are temporarily discontinued. Then these patients who are not delinquent will not be told by mistake that they should be in the clinic.

This definite routine in the operation of a venereal clinic will save time and make more efficient the work of the physician in diagnosis and treatment.

ESSENTIALS OF DIAGNOSIS AND TREATMENT

A tentative diagnosis of venereal infection may be made from the immediate findings, but every patient should have blood taken for tests for syphilis, and should have a general physical examination, preferably stripped, which should include an examination for gonorrhea. This general examination of all persons for both gonorrhea and syphilis should be supplemented by special examinations for the particular disease which is very strongly suspected. Infections with two diseases are so common that syphilitic females particularly should be examined for gonorrhea, and all patients, of course, should have a routine blood test for syphilis. In the examination for syphilis and chancroid, the laboratory procedures usually are the more important, but in watching for gonorrhea, except in the acute stage, the clinical findings are the more significant.

GONORRHEA IN THE MALE

The diagnosis of acute gonorrhea in the male is obvious if the patient presents himself with a purulent urethral discharge coming on in from 2 days to 2 weeks after intercourse. Even in a public health clinic it is well to spare the slight time to make a smear in order to avoid the mistake of thinking that more than one discharge in a hundred is caused by anything but the gonococcus.

When the patient's discharge has ceased he is ready for the tests of cure. When the patient goes through a period of 1 month without any discharge or morning drop, he is given an instillation of 2 c.c. of a 1 per cent solution of silver nitrate. He comes back one month later, if he has no discharge in the meantime, and is given another instillation. In 4 weeks, if he has had no discharge, a large sound is passed. At the end of another month he returns for the passage of another sound.

If all the tests of cure are negative, he is told he is probably cured, but that he should have no intercourse without a condom for the next 6 months. He is told that if he has no symptoms in the meantime he can consider himself cured at the end of that time.

While the majority of cases of acute gonorrhea get well fairly readily under ordinary treatment, a tenth will be found to have a persistent morning drop or other sign of chronic gonorrhea.

The diagnosis of chronic gonorrhea in the male is made on the clinical evidence with such findings as an excess of pus cells from the prostate and various kinds of shreds in the urine. There is little chance of proving the presence of gonococci by smears. Most cases with persisting intracellular gonococci in the discharge should be classified as

acute or subacute gonorrhea, even though the disease may have been present for some time, as such patients require more gentle treatment than the usual case of chronic gonorrhea.

The exact treatment whether by dilating or by massage of the urethra and prostate and seminal vesicles or by stimulating injections and applications will depend mainly on clinical findings. Results of treatment will depend upon the energy, intelligence and experience of the clinician and not upon any textbook routine.

GONORRHEA IN THE FEMALE

The diagnosis of gonorrhea in the female in the acute stage can readily be made on either clinical or laboratory evidence. Smears from the urethra at this time will generally show almost as definite a picture as smears in acute gonorrhea in the male. The diagnosis of chronic gonorrhea in the female is difficult and usually must be made from the history and clinical findings. A profuse vaginal discharge and cervical involvement without obvious cause should be tentatively considered gonorrheal until proved otherwise. Induration of Bartholin's glands and inflammation or induration of the urethra are further evidence of gonorrhea, although not pathognomonic.

A carefully taken smear from the urethra may show gonococci. The tip of a wooden applicator is tightly wound with just enough cotton to cover it and inserted gently almost one-half inch into the female urethra, which is well massaged or "stripped" from below. This applicator is rolled or tapped over one end of a microscope slide to make an impression preparation instead of a smear. Material from the cervix is not so likely to show a good picture of gonococci, but any pus from Bartholin's gland usually will show many Gram negative intracellular diplococci. A good Gram staining method is Jensen's.² It is difficult to diagnose chronic gonorrhea in women and even more difficult to determine when it is cured, as all tests may fail in gonorrhea in women until another male is infected.

Gonorrhea in women can be cured if the coöperation of the patient can be obtained. Routine treatment will clear up most cases without complications if the disease has not already spread to the tubes or produced a severe inflammation of one of Bartholin's glands. The routine of treatment should combine simplicity with efficacy, and preferably not necessitate more than one treatment per week.

Tests of cure are unreliable as the gonococci are not found in smears long before the patient is cured, and complement fixation tests are still less dependable. So we have to rely upon clinical findings such as the absence of any areas of inflammation or abnormal discharge.

SYPHILIS

The diagnosis of syphilis by laboratory methods is the most accurate and satisfactory diagnostic procedure in the clinic. Every patient coming to the clinic should have blood taken for a Wassermann. Suspected primary lesions will in most cases give a positive Wassermann reaction, but one should not wait for this test, for of course in the very earliest stage the Wassermann is negative.

If primary syphilis is suspected, a darkfield examination should be made immediately. A good grade of darkfield equipment should be used or the diagnostic effort will be worse than useless. The combined light and substage commonly known as the Army Medical School type is mentioned only to be condemned. It is best to try out the type of darkfield offered by a manufacturer on mouth spirochetes before purchasing. A cardioid condenser that fastens securely to a rack and pinion substage is part of a satisfactory equipment. A special darkfield objective such as the 60X apochromat with iris diaphragm of Zeiss is little more expensive than the ordinary objective with a separate funnel stop but is much more satisfactory to use. The very bright concentrated filament lamp is more convenient and cheaper than most arc lamps.

The persons using the darkfield should thoroughly digest the directions which should always be supplied by the maker with any form of darkfield. If the spirochetes appear as a row of dots instead of like a corkscrew, the operator of the apparatus is ignorant of the method used for that particular type of darkfield, or the equipment is poor. In either case it is inexcusable and dangerous to attempt to make a diagnosis by such means.

A sensitive Wassermann test will confirm the darkfield findings in 90 per cent of the cases at the time they arrive at the clinic. A negative Wassermann is probable with most sores of less than 10 days duration, but very improbable after the third week of the sore. If the darkfield is negative, the Wassermann should be repeated every week until 5 weeks from the date of the appearance of the sore, and it should be repeated again 1 month or 2 months later before the patient should be assured that he is not infected with syphilis.

A carefully made sensitive Wassermann reaction is still the most accurate diagnostic serum test for syphilis, even though a few laboratories are now doing only a flocculation test. Most of the flocculation tests not only are less sensitive than a good Wassermann test but also are more liable to produce false positives. The simplest flocculation test is Dr. Kline's microscope slide method with his new antigen, which is almost as sensitive as the most sensitive Wassermann, but in

my hands has occasionally produced a weak reaction in the absence of syphilis.

No matter what blood test is used for syphilis, a single positive report should never be considered alone as proof of syphilis. Two positive reports should be received before accepting the Wassermann as proof of syphilis. Three or more weak positives or doubtful tests are necessary as good evidence of syphilis. With continued doubtful reactions, a lumbar puncture may disclose a spinal fluid with an increased cell count and a positive Wassermann. Not only should all positives or doubtfuls be repeated, but all negatives also should be repeated when there is contrary evidence. The repetition of all positive or doubtful reactions should be an automatic routine arranged by the clerk.

The infectious cases of syphilis usually will have either a positive darkfield or positive blood test. The primary lesions and early secondary lesions may be proved syphilitic immediately by the darkfield examination and given immediate treatment.

The microscopical demonstration of spirochetes in some cases of secondary syphilis may be very difficult, even though the lesions are very infectious, but the Wassermann will always be strongly positive. The experienced clinician, however, will not wait for the result of the blood examination, but will make a clinical diagnosis of secondary syphilis from typical lesions and institute treatment immediately. A Kline flocculation test, which can be done in less than an hour, if negative, will rule out secondary syphilis in a difficult case, or will be positive in a case of secondary syphilis.

The dangerously infectious cases are required to adopt extraordinary precautions during the first week of treatment to avoid infecting others. During this week they should have their own eating utensils, keep their clothing out of reach of others, and avoid the company of others as much as possible. After this short period of intensive treatment, they are relatively non-infectious, as long as they continue vigorous treatment, and then need not adopt special measures to avoid the ordinary human contacts.

A routine of treatment should be developed in which nearly all of the patients receive the same drug at their weekly visits to the clinic. A convenient method is to divide the year into 4 quarters of 13 weeks each, and to repeat a definite routine course of treatment 4 times a year with no rest period. Such a routine is described elsewhere.

The length of such routine treatment of syphilis necessary to render the patient permanently non-infectious from the standpoint of public health, in ordinary contacts excluding pregnancy, is only 6

months, but it should be the aim of the clinic, as far as its finances will permit, to cure the patient. If the finances are limited it is better to make 100 patients permanently non-infectious than to spend the same amount of effort in attempting to cure 20 patients, or, as would be more likely, to confine the attention to only 10.

If cure is the aim, the earliest case should receive at least a year of treatment after the blood (and spinal fluid) Wassermann or Kahn test has become negative and remains so. If a specially sensitive Wassermann or Kline flocculation test is used, possibly a 6-months period of continuation treatment with continued negative tests is sufficient. No patient however early he is treated should receive less than a year of vigorous treatment.

CHANCROID

A diagnosis of chancroid uncomplicated by syphilis should not be made and treatment of any kind should not be given until at least two negative darkfield examinations have been obtained. The diagnosis of uncomplicated chancroid is made by demonstrating the absence of spirochetes and the presence of the Ducrey bacillus in serum from the edge of the ulcer.

SUMMARY

The success of a venereal disease clinic will depend upon the interest of the community, the health department, and the local physicians. The enthusiasm and energy of a single individual, especially a good follow-up worker or nurse, is often responsible for clinic efficiency.

Clinic efficiency with limited funds is dependent upon the adoption of simple rules or routines of treatment. The physician in charge of the clinic must be careful not to fall into the rut of merely making diagnoses and giving treatment. The value of the clinic is dependent primarily upon the number of early cases and sources of infection brought in and rendered permanently non-infectious.

Health Education Program in a City of 100,000*

LOUISE FRANKLIN BACHE

Acting Director of Health Education, Department of Health, Syracuse, N. Y.

WHAT ARE your public health education program and budget? This question was asked of health departments in 26 cities of 100,000 population. The replies were interesting. Few seemed to know what the question meant. All of them disclaimed any special health education service, save certain cities whose programs were supplemented by county or outside funds, and were therefore, not thought representative of cities of this size. Some took the query to refer to work done in public health nursing, others to health education in the schools, and still others thought it had some connection with the issuing of annual reports or the work of a communicable disease bureau. A few mentioned occasional newspaper articles, the publication of bulletins and special pamphlets, and the delivering of health talks. Each of their answers was right in part.

For the purpose of this discussion we shall fence off under the title "health education" only the territory represented by the services of the department of health. The question, then, is how can we make the health information existing in every health department more readily available to a given community?

Sales experts tell us that mass selling is the quickest and most economical way of reaching the public. Mass selling, when connected with a department of health, becomes an interpretation of health facts on a city-wide basis. How can we incorporate this feature then in our health department program? The U. S. Public Health Service and the American Public Health Association consider that mass selling or a health educational program may be conducted more effectively in a city of 100,000 if it is developed and carried on under the immediate supervision of a trained and experienced director who shall work under the close supervision of a health officer. Whether this service be included under the head of a separate bureau or whether it be a subdivision in the administrative department, is a matter for each health department to work out for itself; but that it should exist in some form

* Read at a Joint Session of the Health Officers and the Public Health Education Sections of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

in a city of 100,000 population seems to be an established opinion.

Our next task is to finance this division or bureau and set it off with a program of action. The American Public Health Association, in its publication, *Community Health Organization*, states that the budget for health education in a city of 100,000 may be set at \$4,200. A relatively low figure, \$2,200, is assigned from this amount as the salary for the assistant in charge, and \$2,000 as the modest allowance for printing and other incidental expenses.

Turning to *Public Health Bulletin No. 164*, published by the U. S. Public Health Service, whose chapter on health education is written by Harry H. Moore, we find \$9,300 suggested as the minimum expenditure consistent with a reasonably adequate program for an average city of 100,000. The figure is divided in the following way: \$3,500 as salary of the chief of the bureau; \$1,800 for an assistant, and \$4,000 for printing, exhibits, and other incidental expenses connected with the service.

Which is right? The average commercial house assigns from 2 to 5 per cent of its budget for publicity and advertising. Health education represents the publicity and advertising service of the health department.

If we accept the American Public Health Association's estimate of \$217,090 as the budget for all activities of a health department in a city of 100,000 for a year, we find that the amount allotted by this same organization to public health education represents 1.9 per cent of the total health department budget, while the amount proposed in *Bulletin No. 164* equals 4.2 per cent of the total budget. The estimates of our authorities, therefore, range from approximately the minimum advertising rate to some degrees below the maximum one.

Meditating upon these budgets we are forced to admit that the average city of 100,000 which, in the year 1927 has no clearly conceived notion of health education as a separate service of the health department, will be much more inclined to adopt the smaller than the larger budget, no matter what advantages we may list after the \$9,300 figure. Assuming that \$4,200 is the allowance, what is its purchasing powers? Let it be understood that the budget figure covers only current expenses, office space being provided for the health education service as well as necessary permanent equipment.

QUALIFICATIONS OF HEALTH EDUCATOR

A health education program to be successful must be directed by a person of adequate training and experience. Who is the right person? The right person for a health educational job in a municipal health

department should have a sense of news values and the ability to translate technical material into popular terms. As this is an age of training, we shall not choose the health educator by chance but shall select a person for this position who has had a college education and some training in general publicity and advertising. A good newspaper person may be induced to take a short course in publicity and advertising in some of our universities and so prepare for the position, but experience alone in newspaper work is not enough to make the all-round health educator. There must be special preparation for the job. To these qualities add diplomatic salesmanship, without which all other attributes fail.

Demanding such qualifications it is evident that the salary allotment of \$2,200 is not likely to procure a person so equipped, and endowed. For that reason a suggestion is made to appropriate \$3,000 for the salary of a director of health education. The services of a clerical assistant for one week each month will cost \$300. This secretary may be procured from the staff of the health department or engaged outside.

Having paid off our personnel, we find we have \$900 left in our budget. How much of a health educational program can we buy with this limited allowance?

NEWSPAPER MATERIAL

First and most important is the preparation of material for the daily press. Through this medium the health educator reaches more people than in any other way. To get the most out of opportunities offered, the health educator will map out for himself a program like this: Visit each bureau of the department of health daily in search of news material. Couple the news with health educational facts. Train staff of health department in acquiring a "nose for news." Watch for good news pictures of health activities for a good news picture is worth more than the average news story. Prepare feature stories for local papers frequently on some health activity. Keep in close contact with the city editor, the managing editor, the editorial writer of each paper, and with reporters. Hand in to editorial writers interesting topics for discussion. Keep in close touch with the advertising department of each paper because often through them valuable health copy may be inserted in the space of large advertisers. With their coöperation issue special health numbers from time to time to be floated by advertising—the department of health furnishing the copy and censoring the advertising of these numbers. Do not forget the children. Write stories on health for them at regular intervals and publish in local papers. Send health articles to the foreign papers and all house organs.

The second phase is the organization of a lecture service. Through this service the department of health keeps the various clubs, churches, labor groups and other civic organizations in the community in touch with its individual and community program of public health. The service is without charge. The speakers should be the best authorities the community affords on the various phases of health work and disease prevention. The lecture service may be announced verbally by the health educator to the organizations themselves or through the newspapers or by mail, or through all of these ways combined. Each health talk furnishes a news item and serves not only to get over the desired health information but to keep this service constantly before the public. To add the value of visualization to the service, motion picture films may be used. These films may be borrowed from many of the state departments of health and from some of the large insurance companies without charge. If the health department does not own a motion picture machine, it is quite possible to borrow one, or to get some civic organization to donate such a machine. Health talks for adults and health stories for children at the bedtime hour may be broadcast over the radio. They may be told also in the weekly story-hour at the library.

Balancing the ledgers we find that this part of the program is included under the service of the health director, although a minimum charge may be incurred if organizations are notified by mail of the speakers' bureau activities. This amount we shall take from the allotment set aside for postage and office supplies.

MONTHLY BULLETIN

The third consideration is the publication of a monthly bulletin to reach an audience composed of physicians, nurses, social workers and other persons in the community. With a limited budget it seems advisable to mimeograph the bulletin in the health education office. Wide margins, frequent and inviting captions and fitting illustrations may be employed to attract the eye and induce reading. The bulletin may take the form of a news letter from the commissioner of health, or be a digest of health activities. A brief statement of prevailing communicable diseases with comments should be included in either type of bulletin. Fifteen hundred bulletins in a city of 100,000 will be adequate for the interested groups. For this service an allotment of \$510.49 is made. This figure includes the cost of paper, stencils and ink and printing the address of the department of health on every envelope. It purchases the best grade of mimeograph paper. The stencils are cut and run off by the clerical worker assigned to the service. The bulletin is sent out

in a 2 cent stamped envelope. This insures both better postal service and better attention on the part of the addressee. It means that if the bulletin for one reason or another is not delivered, the post office will return it to the sender. In this way the health department is able to keep its mailing list up-to-date. The stamped envelopes are included in the figure quoted for the bulletin.

ANNUAL REPORT

The annual report is the fourth problem. To help in budget saving the report can be mimeographed in the office on letter-size paper. It should be bound in a cover of heavier paper and bear a printed title. The estimate of \$48.60 for a 60-page report is based on an order of 100,000 copies for circulation among the administrators of the city government and a small selected group of interested citizens. To bring this report to the attention of a large number of city taxpayers, the health educator will make a more or less popular digest of it for publication in the local papers.

EXHIBITS AND POSTERS

As a large group of people either never read the newspapers or confine their attention solely to the headlines, or certain features, we realize that exhibits and posters have a decided part to play in every well organized health educational program. To make our budget go as far as possible we seek the assistance of the art department in our schools. A health poster contest is staged among the school children. This insures both publicity and posters. In order to get the necessary exhibits for our work, help is asked of the manual training department in the schools.

Exhibits and posters made in any of the following ways may be used in store windows, shows, fairs, schools, clinics, business and industrial centers. If it is impossible to secure the coöperation of the art department in the schools for posters, pictures may be clipped from magazines and mounted, and appropriate health messages attached. A corner for health books in the public library may be arranged. Ingenuity and a knowledge of mass psychology rather than expense are the factors which determine the success of exhibits. To this phase of our program we allot \$40 to be used in captions for exhibits, mounts for posters, and the purchase of posters if such are needed.

POPULAR LEAFLETS

Now we have \$300.91 of our budget unspent. We need popular health leaflets for our lecture groups, our clinics, and to answer many inquiries that come into the health department office. Our budget is too

limited to enable us to print our own circulars, but most state departments of health have leaflets that may be obtained at a nominal cost. Many insurance and large commercial concerns also have literature which they are glad to distribute without charge. The difficulty lies in the fact that many of the publications offered are drab and uninteresting in form and not likely to intrigue public reading, although there are notable exceptions. Moreover, one has always to watch one's step in regard to these publications to see that the advertiser does not place the wrong emphasis on the value of his product. In many health departments there is a distinct aversion to using advertising of any kind. When this feeling exists it makes the task of the health educator a difficult one. Illustrations and snappy titles used on mimeographed sheets of health facts will be found an aid in intriguing public interest. For this service, which is a most important one, we allot the sum of \$80. This leaves us \$220.91 for necessary office supplies and postage.

As you think over the program you will see that each saving of a dollar has meant extra exertion on the part of the health director and has consumed much time—time which perhaps might better be spent in making more vital contacts. With an increased budget more attention could be given to working out the main features of the program; the monthly bulletin might reach a large audience if the needs of the community seemed to demand this, or the popular bulletin of the American Public Health Association might be adopted and given wide circulation; the annual report might be put into more valuable and lasting form; publications for the various clinics and services of the health department might be issued to meet better the needs of the community.

Every program in health education must be adapted to the place it is to fit. It is well to remember that the person whose nose is too close to the grindstone is apt to miss many opportunities. The budget we have discussed is submitted as a minimum budget for a health education program in a city of 100,000. It is our expectation that the health educator will so sell this service in a few years time that the city fathers will grant the health commissioner an increased fund for carrying on a work so vital to 100,000 of its city's inhabitants.

Endemic Goiter and Public Health*

O. P. KIMBALL, M. D.

Cleveland, O.

ENDEMIC GOITER with its varied manifestations and biological effects upon the human race is an interesting study. We have volumes on this age old disease giving the theories of its origin, its effects on the individual and his descendants and the various methods of treatment from one generation to the next. The purpose of this paper is to correlate briefly the facts regarding this disease at the dawn of our scientific medical era, to interpret the findings through the last century in the light of our present knowledge, and to point the way for progress. We are not thinking in terms of curative medicine, which was the viewpoint for centuries, but always in terms of preventive medicine.

Iodin was first used in the treatment of this disease by Dr. Coindet¹ when he painted goiters with tincture of iodine in 1820. His results and teaching were sufficient to establish permanently a relationship between iodine and goiter.

In 1850 Professor Chatin² of the University of Paris stated that goiter was due to a deficiency of iodine in air, water and food. However, he could not demonstrate this deficiency and his theory was not generally accepted. Then in October, 1858, before the Imperial Academy of Medicine in Paris, a symposium was held on the treatment of goiter with iodized salt. The authors of this meeting, Dr. Rilliet³ of Geneva and Dr. Boinet⁴ of Paris, refer to the work of Dr. Grange of Geneva, who had given before the Medical Society of Geneva his theory on the cause of goiter and advised the use of iodized salt, which he had used several years (one part of iodine potassium to 10,000 parts of cooking salt), as the best method of preventing as well as curing the tumorous enlargement of the thyroid gland.

In 1867 Saint-Lager⁵ published his first volume on endemic goiter and cretinism, and his second volume the following year. This work represents a personal study of many sections of France. The so-called goiter districts were studied as to geological formation, drinking water and vegetation. He believed in general that where the drinking water traversed calcareous soil there was little or no goiter, while in districts where it traversed sandstone deposits goiter was prevalent. He also agreed with the old idea that it is a water-borne disease, but was never

* Read before the Sixth Annual Public Health Conference, Lansing, Mich., December 2, 1926.

able to estimate the etiologic factor. With the new idea that goiter is due to a deficiency of iodine, Saint-Lager had little sympathy, and his criticisms had considerable weight in discrediting this theory. He writes: "Chatin, the originator of this theory, found that in the plains of the River Po goiter was very frequent, yet the air of these plains contains notable quantities of iodine." Saint-Lager does not tell us how he measured this air for its iodine content.

In 1874 Sir William Gull⁶ described in detail a case of myxedema, calling it a cretinoid state supervening in the adult life of women. He stated that this symptom complex was due in some way to a lack of function of the thyroid gland. This is the first scientific statement regarding the functions of the thyroid, and our studies from this period on have to determine accurately the physiology and biochemistry of this important gland. In 1883 the surgeons, Kocher and the Riverdin brothers, got exactly the same symptom complex as a result of total thyroidectomy. This strengthened Gull's theory, and when a few years later McKenzie and Murray showed definite improvement in a case of Gull's disease by feeding a glycerinated extract of sheep thyroid, this theory was considered as established. It still stands out as one of the fundamental facts showing the influence of the thyroid on general metabolism. In 1892, Magnus-Levy showed in a very scientific manner that the thyroid controls the rate of heat production, and that in cases of exophthalmic goiter heat production is markedly increased while in so-called Gull's disease it is markedly decreased.

In 1888 William S. Halsted⁷ with experiments on dogs had shown that if you remove as much as three-fourths of the thyroid, the remaining one-fourth undergoes a hyperplasia and hypertrophy that is histologically the same as is seen in goiter formation. Also during these experiments he found that, while the thyroid in a pregnant female dog was enlarging, the pups' thyroids were undergoing hyperplasia and at birth were definitely enlarged.

In 1895 the relation of iodine to the thyroid gland was again emphasized when Baumann⁸ of Freiburg found by chemical analysis that the thyroid contains iodine; yet the full significance of this discovery was not appreciated for some years. In 1902 the further studies of Baumann and Roos showed that when iodine is stored in the thyroid it combines with the globulin to form what they called thyroglobulin.

Our detailed information on the physiology and biochemistry of the thyroid was worked out by Marine and his associates. Marine and Williams,⁹ studying the histological changes which constantly take place in the formation of goiter, found a definite cycle of changes which is the same for all animals studied. A fall in the iodine store always

precedes any cellular changes. Then comes a decrease in the stainable colloid, followed by change in shape together with multiplication of cells (active hyperplasia) and glandular hypertrophy. They repeated the experiments of Halsted and found that we can remove as much as five-sixths of a dog's thyroid and if the remainder be kept saturated with iodine the cellular changes, which heretofore had been constant, do not occur.

During these experiments they also showed the relation of iodine deficiency to congenital goiter. A female dog with three-fourths of the thyroid removed was permitted to become pregnant and was kept on a diet low in iodine. At birth all of the pups had enlarged thyroids showing the same histological changes as are seen in early goiters. Also the iodine content was below normal. This same female dog was again permitted to become pregnant and was this time given a definite amount of iodine each week so that her thyroid remained normal in size. At birth all of these pups had thyroids normal in size, in histological structure and in iodine content. This experiment has been repeated several times and is of fundamental importance in the prevention of endemic goiter.

In Marine's²⁰ series of different animals, including dog, rabbit, pig, ox and man, the amount of iodine required to keep the thyroid normal seemed to be very constant. The maximum amount of iodine found in normal thyroids was approximately 5 mg. per gm., with an average of 2 mg. per gm. and a total of 40 mg. for the normal adult human thyroid. As long as the iodine content remained above 1 mg. per gm. of dried tissue, no cellular changes would be found, but as soon as the iodine content fell below 1 mg. per gm., or 0.1 of 1 per cent, active hyperplasia and hypertrophy took place. From these experiments Marine states that the normal function of the thyroid depends entirely on iodine. From these same studies came the now famous dictum: Simple goiter is the easiest known disease to prevent.

Although as early as 1870 the farmers of Michigan were preventing endemic goiter and cretinism in their sheep by the use of crude salt from a certain district, yet they did not appreciate what they were preventing or how it was accomplished. The first systematic effort to prevent goiter in animals was applied to the fish-raising industry at the State Fish Hatcheries at Shady Grove, Pa., from 1909 to 1910.²¹ Here an exceedingly small amount of iodine in the water controlled what had come to be known as a serious endemic goiter problem. They are still carrying on this prophylaxis by the use of food rich in iodine twice weekly. This work, which is too well known to be recorded here, proved the fundamental truth of the hypothesis, and gave conclusive

evidence that goiter in animals can be prevented by the administration of a small amount of iodine.

Endemic goiter had been repeatedly stressed as a deficiency disease, and we had stated that there is a definite deficiency of iodine in food and drink in the so-called goiter districts, but a systematic effort at prevention in man was not undertaken until the fall of 1916. This work was started by Marine and Kimball¹² in the schools of Akron, O.

There were 2 important reasons why this work should be started throughout public schools: First, the future of this health measure depends entirely upon the education of the community as a whole; second, in our public schools we have the children at the adolescent period when, as we know from common observation, goiter is most prevalent. Therefore, with the coöperation of the authorities of the Akron public schools, a survey was made of the girls only, from the fifth to the twelfth grade inclusive. Our survey showed that 56 per cent of these girls had definite thyroid enlargement. For practical purposes we did not at that time call anything goiter which could not be easily demonstrated. This means that 56 per cent of these girls had visible goiters. Our plan of prevention was to saturate the thyroid gland twice a year, spring and fall, and to this end we gave each girl, who must volunteer and also show a permit from the parent, 3 gr. of sodium iodide daily in the drinking water over a period of 2 school weeks (10 days), each November and April during the next 4 years.

Of the 2,190 pupils taking 2 gm. of sodium iodide twice yearly, only 5 developed thyroid enlargement; while of 2,305 pupils not taking the prophylactic, 495 developed thyroid enlargement. Of 1,282 pupils with thyroid enlargement at the first examination who took the iodine systematically, 773 thyroids decreased in size; while of 1,048 with thyroid enlargement at the first examination who did not take the prophylactic, 145 thyroids decreased in size. These figures demonstrate in a striking manner both the preventive and the curative effects.

Following the publication of the work in Akron, Klinger¹³ started the prophylaxis throughout the schools of Zurich. Early in 1921 his reports showed even more curative effect in this district than we obtained in Akron. He worked in schools, however, where the incidence of goiter varied from 82 to 95 per cent, while our highest incidence was only 56 per cent. With such a high incidence his results necessarily deal more with the curative effect. Thus of 760 children, 90 per cent were goitrous at the first examination, but after 15 months 643 who were reexamined showed only 28.3 per cent goitrous. During these months each had received 10-15 mg. of iodine each week, using the iodostarin tablets.

TABLE I
RECORDS OF PUPILS TAKING AND NOT TAKING
PROPHYLACTIC TREATMENT

Prophylaxis through the schools was adopted by several Swiss cantons, and the Swiss Goiter Commission after a study of the problem decided that the iodine deficiency should be met as a food problem and soon advocated the use of iodized salt. The use of their so-called Standard Salt was begun in the canton of Appenzell in February, 1922, and just a year later it was extended to the cantons of Zurich, Luzern, St. Gallen and Thurgau. Prophylaxis in the district of Appenzell has been under the close supervision of Dr. Eggenberger." The salt has been examined in his laboratory at Herisau, and during the last four and a half years he has made 2,700 iodine determinations. He has also pointed out some very definite results. He states that before the use of Standard Salt at least 50 per cent of the babies in Herisau were born with a definite, palpable, visible enlargement of the thyroid gland. In the last 3 years he has followed carefully 260 cases without seeing a single congenital goiter, the only prophylaxis being that the mother had used Standard Salt before and throughout the entire period of pregnancy. He further states that in 1922 in the 6-year old child the average thyroid gland surface was 26cm². This sank from year to year to 16, 11, 9, and in 1926 it was only 7cm². In children of the same age in goiter free zones it was 5-6cm².

In 1921, Dr. Muggia²⁵ started the prophylaxis of goiter in the district of Sondrio in northern Italy by giving once a week a ¼ gr. tablet of sodium iodide. His results were striking, as he was working in a district where the incidence of goiter is high. At the end of the school year in 1924 his tabulations include 51 communes, showing more than 18,000 pupils taking iodine (10 mg. chocolate) regularly. In December, 1924, iodized cooking salt (one part in 100,000) was introduced as a prophylactic measure.

In 1925 iodized cooking salt was introduced into Derbyshire, England, and into New Zealand.

During this same period we have carried out goiter prevention in this country by various means. There being no federal commission in the beginning, the work was taken up by the various states according to the method which seemed best to meet their plan of education as well as prophylaxis.

In West Virginia, during the summer of 1922, the prevention of goiter was presented before many of the county teachers' institutes, and during the school year of 1922-23 more than one-third of the schools of West Virginia, city, village and county, carried out prevention by giving every girl and boy who volunteered 1 iodostarin tablet each week. The teachers were also telling them that goiter is a deficiency disease and that it is the easiest known disease to prevent. In general, they taught the people of West Virginia the cause of goiter and the fundamental principles of prevention.

During the same year, practically the same program of prevention and education was started in the schools of Grand Rapids, Mich. The next year, beginning in September, 1923, the state of Washington, with the supervision and direction of the State Health League, started the prevention in one school system in each county, either at the county seat or in an important city. Each child who volunteered was given 1 iodostarin tablet a week.

One of the most important surveys that have been made in this country was that carried out by the State Health Department of Utah in 1924. The first report shows that 71,201 school children were examined. Of these, 31 per cent of the boys and 54.4 per cent of the girls had goiter. By the end of that school year 10,000 children were carrying out the prophylaxis by the use of 10 mg. of iodine once a week, and this work has been extended very greatly since that time and will ultimately include the whole state.

New York has an endemic goiter problem in only 5 of her northern counties. The state health department has encouraged each county health department to carry on instruction as well as some preventive measure. Syracuse has given this instruction together with the opportunity for each child to get an iodostarin tablet (10 mg. of iodine) each week. The general use of iodized salt throughout these counties is now being urged.

In 1924 the Michigan State Health Department¹⁰ made a complete goiter survey of 4 counties of Michigan, beginning on Lake Superior with Houghton County and continuing with Wexford, Midland and Macomb in a diagonal line across the state. In addition, the iodine content of the water supply of each county was determined. Stated briefly, the incidence of goiter was found to be inversely proportional to the

quantity of iodine in the drinking water. In Houghton County, where 13,725 children were examined, it was found 58.1 per cent of the boys and 70.5 per cent of the girls had goiter. The iodine content of the water supply of this county was exceedingly low, a mere trace. In Wexford County, 47.6 per cent of the boys and 63.4 per cent of the girls were goitrous; the iodine content of this water was slightly higher than that of Houghton, being 50 parts per 100 billion. In Midland County, 24.4 per cent of the boys and 41.1 per cent of the girls were goitrous; the iodine content of the water supply of this county averaged 730 parts per 100 billion. In Macomb County, where the iodine content of the drinking water averaged 880 parts to 100 billion, the incidence of goiter was 20.1 per cent of the boys and 32 per cent of the girls.

Immediately after this complete survey, the state health department undertook the gigantic problem of educating the entire state by giving these facts, together with suggestions for the prevention of goiter. To this end an appropriate letter was sent to each member of the medical profession, to school authorities, and through the schools to the parents throughout the entire state. By coöperation among the salt manufacturers, the wholesale grocerymen and the state health department, it was agreed that after May 1, 1924, an iodized salt which should contain 1 part of sodium or potassium iodide to 5,000 parts of table salt would be sold throughout the entire state. This program has been carried out consistently, and it is estimated that in some counties up to 95 per cent of all the table salt used is the iodized salt.

We have had the opportunity of making a resurvey in Wexford County only. This was made in October, 1925, and showed that the incidence of goiter had decreased just 25 per cent in 18 months. The only method of goiter prevention employed in the county during this period was the use of iodized salt.

When the work was started in Akron, we had no standards to guide us, but we used the amount which we considered sufficient to saturate the thyroid gland and at the same time be well within the province of safety. The exact amount necessary to prevent goiter was being considered. From Marine's studies of physiological needs we estimated that approximately 200 to 300 mg. per year of iodine is used by the normal adult. It was from these estimations that we suggested the use of 10 mg. of iodine a week throughout the entire school year of 40 weeks. This is higher than the amount recently advocated by Breitner²² of Vienna, who concludes that, to meet the physiological needs of iodine and prevent goiter, each individual need have only 2 mg. of iodine a week, or 100 mg. a year.

Since McClendon²³ improved the method of determining exceed-

ingly small amounts of iodine in 1922, considerable work has been done on actually measuring and comparing the amount of iodine in the water and food in so-called goiter districts and goiter free districts. McClelland has made sufficiently widespread determinations of the iodine content in the water supply to map out practically the whole United States according to a very low or a comparatively high iodine content in the water. The water of Lake Superior and the surrounding districts contains, according to accurate chemical analysis, approximately 1 part of iodine to 100 billion parts of water. By the same analysis the water in the lower Mississippi valley contains 10,000 to 15,000 parts of iodine to 100 billion parts of water, and some of the deep wells of Texas show more than 18,000 parts.

The iodine content of water is only a fair index to the iodine content of the food raised in these districts, and by careful estimations the iodine content of vegetables and grain is from 100 to 1,000 times larger in the so-called goiter free sections than it is in the Lake Superior region, which is one of the districts most severely afflicted with goiter.

By chemical analysis, McClelland measured the iodine content of the food and drink of an average sized normal young man (goiter free) for a period of 3 days. He also measured the amount of iodine excreted by the body during the same period. The intake of iodine was 0.057 mg. and the amount excreted for the same period was 0.021 mg. From this we have a retention of 0.036 mg. in 3 days, or an actual retention of 0.012 mg. of iodine every day.

Von Fellenberg¹⁹ in Germany performed on himself an iodine metabolism experiment covering a long period. His food intake was at first not normal but intentionally low in iodine. In the latter part of the experiment iodine was added in the form of potassium iodide or cod-liver oil, sardines, watercress or butter. Von Fellenberg's low iodine diet contained 0.0143 mg. a day. He excreted about the same quantity. On adding iodine in various forms to this basal diet, he increased the excretion but not to the extent of intake, so that he obtained a positive iodine balance. From this experiment we find that the body uses up or excretes a definite amount of iodine regardless of the intake. We can state that an average sized young adult with normal metabolism and a minimal amount of physical exertion, all factors being reduced to a minimum, still excretes 0.0143 mg. of iodine daily. From the amount of iodine in the water and common foods of our goiter districts, McClelland estimates it would require 10 years for a normal adult to accumulate 40 mg. from these natural sources. This 40 mg. is the average amount that Marine found in normal adult thyroids.

That endemic goiter may be prevented by the general use of a food

rich in iodine has been shown by Jarvis, Clough and Clark²⁰ in their study of goiter in the Pemberton valley, British Columbia. Endemic goiter and cretinism have been very prevalent among the white settlers and their domestic animals in this valley, yet no cases of goiter could be found among the inhabitants of an Indian village located on the same spot in this valley since many years before settlement by the white man. These authors conclude that the Indians, also their pigs, get sufficient iodine to keep their thyroids normal from the large amount of salmon that is annually consumed.

SALT AS A NATURAL SOURCE OF IODINE

During 1921-22 Hayhurst²¹ was pointing out that our common table salt has been the source of important food elements, especially iodine. He believes that our present-day methods of refining, whereby every trace of iodine is removed, have in some sections played an important part in the increasing incidence of endemic goiter. Convincing evidence of the truth of this teaching was found in our study made in West Virginia, more especially in the Kanawha River valley. In the spring of 1922, when surveys were made to determine the incidence of goiter throughout this section, we were told by several of the older physicians in Charleston that before 1900 endemic goiter was an exceedingly rare entity in this valley, but that soon after this date all the doctors had noticed a definite increase in simple goiter, and our survey of the schools of Charleston and Huntington showed that 60 per cent of the school girls had enlarged thyroids. This was indeed a challenging problem, and with the assistance of the state health department we found after considerable study that the condition as just stated was exactly true of the section, and that the only change in food or water was in the table salt. Until about 1900 all the table salt used in this valley came from salt wells in this region, and even today you can see along the river old shacks that 25 years ago marked a salt well. It is within the memory of every citizen 50 years of age that the table salt mined and used in this vicinity was a crude salt, described by everyone as being coarse and containing dirty brown particles. In 1898 the salt companies of Ohio and Michigan worked out and put into actual practice the new process of refining crude salt, as a result of which this whole section was within a few years flooded with pure fine white salt. Naturally, the local salt companies with their crude, dirty brown salt could not compete. As stated previously, the only change in food or water was in the supply of salt. It followed that within a quarter century the incidence of endemic goiter was as high in this valley as around the Great Lakes.

We find a similar interesting clinical study of prevention of goiter by the use of an original salt rich in iodine reported by Heinrich Bircher in 1875-80. His comparison of the incidence of goiter in different cantons of Switzerland was most striking. This study was interpreted more fully by H. Hunziker²² in 1915, from whom we get important data. He found that, from 1870 on, the chemists at the salt mines in the region of Bex (Switzerland) had made careful report on the iodine content of this salt, which is unusually rich in iodine. He also found that the canton of Waadt, either by accident or design, had obtained and still holds a complete monopoly of the salt from this district. Incidentally, the neighboring canton of Freiburg procured its salt from an entirely different source, which by actual analysis has shown little or no iodine since this period. The geology, the physical geography, the inhabitants and the foodstuffs in general in these 2 cantons are practically the same, the only difference being that for 50 years the canton of Waadt had used a salt which contains considerable iodine and the canton of Freiburg had used an iodine free salt. From the army statistics over this period, as shown in Table II, goiter has been 5 times as frequent in the canton of Freiburg as in the canton of Waadt.

TABLE II
RECRUITS UNFIT FOR SERVICE 1875-80
(FROM CENSUS REPORTS)

<i>Waadt</i>	Recruits	Goitrous	Per Cent	<i>Freiburg</i>	Recruits	Goitrous	Per Cent
Trey	20	0	0	Torny	18	4	22
Marnand	13	1	8	Chatonnave	23	5	22

Lovatens	15	2	13	Billens	13	2	15
Sarzens	5	0	0	Hennens	10	3	31
Brenles	14	1	7	Villaranon	6	3	49
Total	127	8	6		242	73	30

These two demonstrations from West Virginia and from Switzerland would indicate that in some sections practically our total amount of food iodine is from common salt. It further emphasizes the point that a very small amount of iodine, if used continuously, is able to keep the thyroid gland saturated and thereby prevent endemic goiter. The small amount of iodine that is estimated by McClendon and von Fellenberg as representing the basal needs of the body just about equals that which would be found in the crude salt cited above.

This relationship, as set forth by Heinrich Bircher in 1883 and by the recent studies of von Fellenberg under the Swiss Goiter Commission, has been the basis for the iodine content of the so-called Standard Salt which has been used in Switzerland since 1922. They estimated the average individual would use 5 kilos of salt in a year, or approxi-

mately 11 pounds, while in this country our best estimations have placed the amount used by each person at 7 pounds a year. Their Standard Salt contains 5 mg. of potassium iodid per kilo of salt, which would give in a year 25 mg. of potassium iodid to each individual using 5 kilos or 11 pounds of salt; while in Michigan an adult using 7 pounds of salt (1 part potassium iodid to 5,000 of salt) would get 10 grains of potassium iodid or 400 mg. of iodin, the same as a child getting one 10-mg. tablet a week.

Early in 1921, Sloan ²² advocated the use of iodized salt as a prophylactic, and suggested that one part to 5,000 be used. The immediate result of this suggestion was the introduction of a prepared salt prepared by a wholesale drug house and sold through the drug stores.

POSSIBILITY OF HARM

Since the beginning of preventive work in 1916 through the schools of Akron, we have recognized the possibility of harm, have constantly watch for any untoward effects in our studies, and have had our colleagues do the same. It was predicted by some in 1916 that we should have a regular epidemic of exophthalmic goiter.

This "epidemic" was discussed as long ago as 1858. As previously stated, there was in that year a symposium on the treatment and prevention of goiter before the Imperial Academy of Medicine in Paris. Dr. Rilliet of Geneva stated that he had for several years used iodized salt, one part of potassium iodid to 10,000 parts of cooking salt, following the teaching of Dr. Grange of Geneva. He had used this in the treatment of large goiters in many of his families, and at this time he is reporting 4 cases that presented what we would now diagnose as toxic adenomatous goiter. These were all of longstanding nodular goiters—3 women, age over 60 years, and 1 man age over 45. As Dr. Rilliet expressed it, these members of different families had attained in different degrees an ensemble of symptoms characterized by emaciation, palpitation, acceleration of pulse, general tremor, accompanied with great general nervousness and a marked diminution of strength. All of these cases were cured, however, by "rest, asses' milk and preparations of iron." Some years afterward, Dr. Rilliet goes on to say, the man of 45 passed many weeks at the seashore and was not slow to develop again the train of symptoms already described. He concludes that the patient's second intoxication was from the inhalation of iodin from sea air.

Dr. Rilliet's conclusions sound very much like some we have heard within the last year: (1) The long continued absorption of small doses of an iodin salt mixed in the water, air or food is not always without

danger. (2) The inhabitants of certain localities are more than others exposed to iodine intoxication. (3) This special susceptibility depends perhaps on the small quantity of iodine one receives from the water, the air or the food in these countries. (4) Iodine intoxication is perhaps more likely to do harm when the medicine is given in small doses than in large doses and as a preventive than as a cure of a local and confirmed diathesis.

At the next meeting of the Imperial Academy of Medicine at Paris, October 26, 1858, Dr. Boinet of Paris addressed the Academy in a letter on "Food Iodine—The Intoxication Shown by Dr. Rilliet (of Geneva) Has Never Existed." He accused his colleague of being imposed upon by the "axiom which often misleads, that *post hoc, ergo propter hoc*." He was also impressed by the fact that only 4 cases had been reported from a country where goiter was very frequent. Since Rilliet states that he had treated many families with iodine, and several of his colleagues were so treating many goiters, why should we see only 4 cases reported? Suffice it to say that this argument was not decided, and has been given here to show the futility of just such arguments within the past year.

After this discussion, the fear of possible danger to a few seemed to carry much more weight than the evidence of benefit to the many, and by 1870 the relation of iodine to thyroid enlargements was practically discredited or forgotten. Now, however, with the background of 40 years of scientific investigation, together with the definite results being reported in Switzerland with their Standard Salt and the data already collected in this country from the use of much larger amounts of iodine, it would seem that the prevention of goiter is on a scientific and safe basis. However, we are seeing reports in our medical literature of cases of exophthalmic goiter in persons who had previously used prophylactics such as iodized salt, and they are spoken of as exophthalmic goiters caused by the use of iodine in these small amounts, without a true appraisal of all the other factors that have been considered etiologic for the past 50 years. The ease with which this fallacious conclusion can be made was emphatically called to my attention during the reexamination of the children of Marion County, O., in October, 1926. Two girls, age 14 years, with moderate-sized, nodular goiters, were seen who on examination in 1925 had been classed as having moderate-sized congenital goiters. They had both used iodized salt during the entire year, and now showed every evidence of rather severe hyperthyroidism. On further investigation, however, it was found that one had been taking thyroid extract since March, 1926 (7 months), and the other had been started on Lugol's solution in July and after

this had used iodex ointment freely on the neck once a day. This proves nothing against the prevention of goiter, but shows the dangers of careless treatment.

In the work in Akron, if you will consider 2 gm. of sodium iodid over a period of 2 weeks as 1 treatment, then we gave more than 10,000 treatments, and the total of bad results was 10 cases of mild iodid rash with never any symptoms of hyperthyroidism.

In Switzerland, from the use of iodostarin in some cantons for as long as 8 years and the general use of iodized salt in several cantons for 4½ years, Dr. Eggenberger states they have not seen a single case of harm that could reasonably be credited to the general use of iodine in the effort to prevent goiter. In 1926 he made a special study " of the few cases in which it was reported that harm had been done by the prophylaxis, and gives this summary: "In Canton Appenzell A.Rh., with under 55,000 inhabitants, in 4½ years there has not come into view a single case of harm from the use of iodine through governmental iodized salt for cooking, although I follow each doubtful case which is mentioned to me by my colleagues. It would be instructive to go through the many sources of error which lead falsely to the diagnosis of iodism. The most interesting was the panic anxiety of a certain person who already had gastric symptoms and palpitation from the salt before it was iodized. In the Swiss statistics there figures a case of alleged death produced by the use of iodized salt in which case it was later known that the patient never had occasion to get iodized salt."

Dr. Muggia reports no bad results from the use of 20 mg. of iodine weekly, and at the close of the school year in 1924, 10,000 children were taking this amount systematically.

Briefly, we have never seen an authentic case of hyperthyroidism in children that could by any stretch of the imagination be attributed to the prophylaxis of goiter through the schools. This point seems agreed upon by all. However, the old argument about longstanding goiters in adults put forth by Rilliet in 1858 seems to live on.

In an attempt to answer the question, a large number of hyperthyroidism cases were studied for a history of iodine intake before onset of symptoms or as treatment for simple goiter. All these cases were seen in the Cleveland Clinic in 4½ years, from March, 1921, to September, 1925. During this time 2,659 cases of hyperthyroidism were studied, and all who had used iodine in any form previous to any symptoms or as treatment for simple goiter by physicians, were listed as cases of induced hyperthyroidism. This report by Kimball " was published in the *Journal of the American Medical Association*, November 28, 1925, with the summary given in Table III.

TABLE III

INDUCED HYPERTHYROIDISM

Total number of cases of hyperthyroidism	2,659
Total number of cases of induced hyperthyroidism	309 (11.6%)
Induced by:	
Iodized salt	6 (2%)
Self-medication	37 (12%)
Medical treatment	266 (86%)

It was stated in the article, but with insufficient emphasis, that during this study we had seen many cases of middle age women with long-standing nodular goiters that had developed hyperthyroidism with exactly the same history as the 6 listed in the foregoing table under "Iodized salt," only they had never used iodized salt or any iodine. Therefore, in the case of the 6 the iodine they received from iodized salt is not necessarily an etiological factor; their having used iodized salt and later developing hyperthyroidism is probably only a coincidence.

In the past 6 months we have studied 33 cases of severe exophthalmic goiter, and of this number only 5 had ever used any iodized salt. These 5 responded to the use of large amounts of iodine, such as 500 mg. daily, exactly the same as the 28 others. Also the same factors—focal infection, shock, exhaustion and the history of adenomatous goiter—were to be considered in the 5 as in the 28. And further on this point, Dr. Allen Graham from a close study of the surgical goiter cases in Lakeside Hospital states he has never seen a case where he could say with any satisfaction that the hyperthyroidism was a result of iodine in amounts used in general prophylaxis, especially in iodized salt.

By emphasizing the tremendous harm this public health measure has suffered from unscientific articles in which personal opinion has been given instead of scientific data, we commit ourselves to a program of real investigation to learn the truth of the situation. As a result of surveys, iodine determinations, teaching and encouragement from the State Health Department in Michigan since 1923, we have in Michigan more basic information than anywhere else in the world. If all this information were available, no doubt our big questions would be answered by indisputable figures. Therefore, the next important step is getting and correlating this information.

CONCLUSIONS

Every survey or study only emphasizes the importance of prevention during pregnancy. The relation of these congenital defects to the adenomatous or tumorous conditions of later life is more and more appreciated with each careful study. We all know the disappointments in our attempts to control or treat these tumorous thyroids. Therefore,

we cannot stress this point too strongly, and in endemic districts we need the assistance of all prospective mothers and of the physicians who educate and direct them through this important period. It is during pregnancy that the general use of iodized salt is of greatest value. For those under the supervision of their physicians or those who accept the responsibility themselves, one or two iodostarin tablets a week throughout pregnancy and lactation would be excellent.

The history of this problem for the past hundred years teaches most emphatically that the treatment of goiter is very unsatisfactory and accomplishes little toward the control of the disease. Those attacking the problem from the viewpoint of preventive medicine—physiologists, biochemists and public health organizations—have accumulated sufficient evidence to justify the assertion that endemic goiter is the easiest known disease to prevent. By further detailed study of the fundamental principles underlying the cause and prevention and with the constant application of scientific data by the state health organizations, we should see the fulfillment of our prediction: Within another generation there will be no endemic goiter problem.

Bureau of Laboratories and Research, Department of Health, Chicago, Ill.

A BANQUET on September 23, 1926, was attended by approximately 1600 members and guests of a Florists' Association at a large hotel in Chicago. A few hours after the banquet some of the guests became ill. Within 24 hours a large number were affected. The symptoms were abdominal cramps, diarrhea, headache, and in some instances nausea and vomiting.

The Department of Health was not notified of the occurrence until September 26, three days later, when an investigation was begun to determine the causative agent. At this time many of the guests had left the city, a fact which rendered it difficult to estimate definitely the number taken sick.

A list of the guests at the banquet was obtained from the local branch of the association; among them were approximately 90 persons who lived in Chicago, and from these, data regarding the number who became ill, the symptoms, the articles of food eaten and not eaten by those who were ill, were obtained.

The data indicated that between 50 and 60 per cent of those present were ill. The information on this point, however, was conflicting. At the same time 1000 guests, not at the banquet, were being served at the hotel. None of these were taken ill. Moreover the hotel management reported no illness on the part of the waiters and other help, a great many of whom had partaken of food served at the banquet.

From the initial survey of the symptoms of some patients, it was decided that the outbreak was probably one of food poisoning. In order to ascertain the probable cause of the outbreak the following procedure was carried out:

* Read at a Joint Session of Laboratory and Food and Drugs Sections of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 17, 1927.

1. All those who had prepared and served the food were required to submit to examination by the Department of Health. The results of these examinations indicated that none of the personnel of the hotel were carriers of pathogenic intestinal organisms.

2. A list and history of all the foods served at the banquet was obtained. This was checked against the previous list of foods eaten and not eaten by those taken ill and those not taken ill, obtained from the 90 guests living in Chicago. The survey brought out the fact that the food had been properly prepared and handled in the hotel. It showed that most of those who were not sick had not eaten the sea food canape (containing crabmeat); whereas, those who were sick had partaken of it. It was evident, however, that if the sea food was at fault, not all of it was contaminated.

3. Samples of several of the lots of foods served at the banquet were obtained and examined at the laboratories of the Department of Health. These foods included crabmeat, ripe olives, pineapples, jelly, mushrooms, drinking water and charged water. All save the crabmeat, consistently gave negative results both chemically and bacteriologically. The crabmeat, however, yielded an organism, which on preliminary examination appeared to belong to the *Salmonella suipestifer* group. Members of this group are known to be occasionally associated with food poisoning. It is generally believed that this type of organism is of animal origin and gets into food through contamination by rats, mice, etc.

The organism on further and careful study was found to have the following properties:

Morphology—It was small, Gram negative, non-sporeforming, and sluggishly motile.

Agar Slant—It gave a moist, smooth, translucent, and abundant growth.

Broth—The medium became turbid; there was a thin pellicle and some sediment.

Litmus milk—The medium became acid in 24 hours, and alkaline in 48 hours.

Indol—The test was negative.

Gelatin—Gelatin did not show liquefaction.

Sugars—Dextrose, maltose, mannite, galactose, trehalose, xylose and dextrin were fermented with production of acid and gas.

Arabinose, levulose, and rhamnose were fermented with acid production but no gas.

Adonite, erythrite, inosite, inulin, lactose, melezitose, raffinose, salicin, and sucrose were not fermented.

Culturally the organism resembled the *Salmonella suipestifer* very closely.

In order to ascertain more fully whether the organism might be *S. suipestifer*, it was tested against *suipestifer* antigen obtained from the University of Chicago and against antisera from rabbits injected with pure cultures of *S. suipestifer*, obtained from the University of Chicago and from the American Type Culture Collection. Six such strains were used to immunize rabbits and yielded sera of high homologous titre for all save one strain. None of these antisera would agglutinate the crabmeat organism. Immune antisera, obtained by injecting washed cultures of the crabmeat organism, failed to agglutinate the pure live strains of *S. suipestifer*. However, the organism was agglu-

minated by its own homologous antiserum in high dilutions. The results throw doubt upon the theory that the organism is definitely a member of the *S. suispestifer*. However, some workers have found that there are certain strains of this group of *Salmonella* which do not agglutinate with heterologous antisera of the species.

To test the pathogenicity of the crabmeat organism on laboratory animals the following experiments were carried out:

The organism was grown in dextrose broth at 37°C. for 24 hours; 1 c.c. of the culture was then injected intraperitoneally into mice. Death occurred within 48 hours in 4 of the 6 mice injected. None of the control mice died. Injections of washed suspensions of the organism also resulted in the death of 5 out of 8 mice in 48 hours. The organisms were then grown in a veal infusion broth containing 2 per cent of Witte's peptone, and 0.1 per cent of dextrose with a final pH of 7.2.

Injection of the cultures, filtrates and washed organisms grown in this broth, all resulted in the death of a high percentage of the mice when 1 c.c. was injected.

Again experiments were tried using Berkefeld filtrates heated to 56°C. for 30 minutes. The heated filtrates did not cause the death of the mice injected.

Some of these results were suggestive of a soluble toxic substance. In order to determine whether we were dealing with a true toxin, attempts were made to obtain protective sera against the filtrate of these organisms. It has been shown by Ecker,¹ Geiger, *et al.*,² and Branham³ that members of the paratyphoid-enteriditis group produced soluble toxin-like substances.

Rabbits were therefore injected intravenously at frequent intervals with sterile filtrates of the "crabmeat" organism.

The antisera from these rabbits failed to protect mice injected with the unheated filtrates.

While this work was in progress another investigation was being carried out on the flora of ground meat obtained in the Chicago market. These organisms were isolated by streaking a portion of the sample of ground meat upon the surface of Endo's medium, incubating the plates for 24 hours at 37° C. and picking the colorless colonies from the surface of the medium. The colonies so picked were purified by repeated seeding in fluid Endo's agar at 45° C. and pouring plates for the deep colony method of isolation.

The properties of the 100 organisms thus obtained were studied in the following media: tryptophan water for 5 days at 37° C. to determine indol production, 14 per cent gelatin for 30 days at 20° C. for

proteolytic enzymes, litmus milk and various 1 per cent carbohydrate media for fermentative changes. The reactions were read in litmus milk in 5 and 15 days, while in the carbohydrate media the results were read at the end of 5 days of incubation at 37° C.

Sixty-two organisms of the 100 selected for study agreed substantially in their cultural reactions with the *S. suispestifer* group while 2 gave reactions similar to *Salmonella icteroides*. The remaining organisms were classified in the *B. proteus* and *B. cloacae* groups.

The organisms tentatively classified as *S. suispestifer* failed to agglutinate with a known *S. suispestifer* antiserum of high titre. The known suispestifer organisms likewise failed to show specific agglutination with antisera prepared from 2 of the unknown organisms.

These studies combined with the work of Geiger, Ward and Jacobson¹ on oysters, carried out in this laboratory indicate that there are a number of organisms associated with various foods, but particularly meat products, that are members of the paratyphoid-enteriditis group. Many of them do not lend themselves to classification with any of the better known organisms. Others fall in the classification of the *B. proteus* or *B. cloacae* group. The presence of any of these groups seems

to indicate unsatisfactory sanitary methods of handling of the foods in question and may be responsible for the outbreaks of gastrointestinal nature.

The rôle of these organisms in food poisoning outbreaks has not been definitely determined, but it is apparent that they are potentially dangerous, for it is well known that several of the better known bacteria of these types do cause food poisoning outbreaks.

The Growth of the Birth and Death Registration Areas*

IN 1924 the slogan was evolved "Every State in the Registration Area Before 1930." When this slogan was first used, there were 31 states in the birth registration area and 38 in the death registration area. In 1925, at St. Louis, a special committee of the Vital Statistics Section was appointed, with Dr. Dublin as Chairman, to aid in the completion of this task.

There has been excellent coöperation everywhere, and as a result of the united efforts of federal, state, city, and welfare agencies of all kinds, not overlooking contributions of over \$30,000 from the insurance companies and the Rockefeller Foundation, there are today 40 states in the birth registration area and 42 states in the death registration area. The following 6 states are still outside of the death registration area: Georgia, Nevada, New Mexico, Oklahoma, South Dakota, and Texas. The 8 states still outside the birth area are the 6 just mentioned and Colorado and South Carolina.†

Registration promotion campaigns have just been completed in Oklahoma and Georgia, and these 2 states are now being tested officially by the U. S. Census Bureau to ascertain whether they are registering at least 90 per cent of their births and 90 per cent of their deaths. Other campaigns are now under way in Colorado, South Carolina, and Texas. New Mexico is just ready to start a drive, and we are hopeful

* Report of the Committee to Aid Completion of the Registration Area before 1930, delivered before the Vital Statistics Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

† Georgia and Oklahoma have recently been admitted to both areas.

that slight modifications will be made in the registration laws of Nevada and South Dakota at the next sessions of the state legislatures in 1929, so that these states will be able to qualify for admission during that year.

Briefly stated, a successful registration promotion campaign requires two things: (1) A diagnosis of the trouble, and (2) the application of proper remedies.

Diagnosis—A careful study is made of existing conditions in the state in an endeavor to locate the registration defects, whether connected with the state office, the local registrars, or with the physicians and midwives, and to determine whether there is any lack of public sentiment in favor of better registration. Unusually low birth rates or death rates in any section of a state immediately suggest defective registration, though further investigation may prove that such rates are due to other causes.

The names of many delinquent physicians and midwives are suggested by noting in the official registration records that for many infant decedents records of births have never been filed. Many delinquents are revealed by checking against the official birth records independent lists of recent births—lists obtained from the official test cards returned to the Census Bureau and from information given by mothers at county fairs, or from information obtained by women's clubs as a result of a house to house canvass, or from cards obtained by the school census enumerators.

Remedies—Under the direction of the state commissioner of health are gathered together as many capable campaign workers as possible from state, federal, and volunteer welfare agencies. These workers then go to those parts of the state which have shown most defective registration, and endeavor to convert the delinquent registrars, doctors, midwives, and others to a realization of the importance of good registration. While making such tours the campaign workers actually collect hundreds of birth records which have never been filed.

Where publicity is needed, posters are put up in the post offices; articles are written for the press; and the chambers of commerce, the Boy Scouts, and welfare agencies are called upon for help.

In terms of population 87.3 per cent of continental United States is now included in the birth registration area and 91.3 per cent in the death registration area. In terms of area, this would be 72 per cent and 76.5 per cent.

If the task ahead is considered in terms of population, the goal does not seem so far away, but when one realizes that 28 per cent of the land area is still outside of the birth registration area and that 23.5

per cent outside of the death registration area, the magnitude of the task ahead is very evident. In a word, the few states still outside are on the whole so thinly populated that tremendous distances must be covered to reach the people and to sell to them the idea that the registration of births and deaths is desirable. Texas alone is bigger than the combined area of the following group of 13 states: the New England states, New York, Pennsylvania, New Jersey, Delaware, Maryland, West Virginia and Virginia, and the land area of the other 7 states still outside the birth registration area is considerably greater than twice the land area of Texas. A realization of this tremendous area still to be brought within the fold in the short period of two years, will convince anyone that our only hope of reaching the goal on time rests upon the full coöperation of every agency. More workers and more funds are needed.

Child Welfare in Mexico

THE Government of the Federal District of Mexico began in October to publish a monthly periodical, *El Nino* (The Child), devoted to child welfare. The periodical consists of four sections, which deal respectively with medicine, including pediatrics and hygiene; psychology, including vocational guidance; education; and social welfare.

THE insanitary conditions under which the children of the poorer classes in Mexico City are living have attracted the attention of the Department of Health of that city. The department has ordered its inspectors to visit all homes, particularly those in the working-class suburbs, in order to investigate the living conditions of the children. Measures for the improvement of the situation will be taken according to a plan prepared by the Department.—*El Nino*, Mexico City, vol. 1, No. 2, 1927.

Bacterium Abortus Infection in Man*

The Results of the Agglutination Test Applied to More Than
10,000 Human Sera

JAMES G. McALPINE, PH.D.

Storrs Agricultural Experiment Station, Storrs, Conn.

and

FRIEND LEE MICKLE, M. S., FELLOW A.P.H.A.

*Director, Bureau of Laboratories, State of Connecticut, Department of Health,
Hartford, Conn.*

SINCE the work of Evans (1918) proved the close relationship between *Bact. abortus* and *Bact. melitensis*, the possibility that *Bact. abortus* might be pathogenic for human beings has been constantly present in the minds of many investigators. During the past two years approximately fifty cases in which *Bact. abortus* has been incriminated as the causative factor have been reported in the United States. In all these patients, the characteristic symptom has been an intermittent type of fever somewhat resembling typhoid. Very recently one case of infection of the genitourinary tract of a woman has been cited by Belyea (1927).

For several years, the Storrs Agricultural Experiment Station has tested by the agglutination and complement fixation reactions a large number of dairy herds in this state. From the data so obtained, it appears that at least 90 per cent of the herds are harboring *Bact. abortus*. Since the mode of spread of this type of disease has been assumed to be through the ingestion of raw milk from infected cows, it would seem that if the organism itself were pathogenic there should be a fairly large number of human beings in the general population infected with the disease. These may have been diagnosed as suffering from other clinical entities, but the agglutination test applied as a routine procedure in a large number of human sera should give more information on this point.

METHODS

The only method which seemed feasible was the application of the agglutination test using a *Bact. abortus* antigen to the human sera

* Read before the Laboratory Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

which were received at the State Department of Health, Bureau of Laboratories, for the Wassermann reaction. Bassett-Smith (1925) tested 130 Wassermann samples in England and found two sera giving positive agglutination in 1 in 40. The objection which might be advanced that these samples coming from persons who showed no real clinical symptoms of *Bact. melitensis* infection might negate the results of the experiment, of course, is valid, but inasmuch as it seemed impossible to obtain numerous sera by any other means, it was the method employed in this work. The results obtained should give some idea of the number of persons in the general population of Connecticut whose sera react to the agglutination test.

The serum was separated from the clot as soon as it was received at the laboratory and after the Wassermann and Kahn reactions were run, it was preserved in the icebox until the agglutination test could be performed. Any samples showing bacterial growth or a large amount of hemolysis were discarded. The antigen employed was made from four strains of *Bact. abortus* coming from different sections of the country whose agglutinability had been carefully checked. These strains were grown for 24 hours on 1 per cent glycerin Fairchild's agar, and from these, transplants were made upon plain Fairchild's agar and incubated for 48 hours at 37°C. The growth was harvested with a small amount of 0.4 per cent carbolized physiological saline and diluted for the final test to a nephelometer 1 on the MacFarland scale. This diluted antigen was distributed in small test tubes in 2 c.c. amounts and the serum added to make final dilutions of 1 - 25, 1 - 50, 1 - 75, 1 - 100. After the addition of the antigen the tubes were carefully corked and shaken, incubated for 48 hours at 37°C. and one reading was made on their removal from the incubator and a second after 24 hours at room temperature. The results were recorded on the 4+ scale, i.e., 4+ indicating complete flocculation and clearing, 3+ and 2+ indicating partial reactions and 0 a non-reactor.

Inasmuch as the names of the patients for the Wassermann reaction cannot be divulged, a number system was used on all samples. Whenever a serum showed 4+ reactions through the 1 - 100 dilution a questionnaire was sent out by the State Commissioner of Health to the attending physician. This asked for the sex, age, and occupation of the patient, a description of the symptoms, whether he had used milk either raw or pasteurized; and requested a second sample and, if possible, a blood culture. Whenever a second sample was received, the dilutions were increased to 1 - 200.

From November, 1926, to July, 1927, a total of 10,157 human sera were tested. Of this number 63, or about 0.6 per cent, showed practic-

ally a complete reaction in the four dilutions used and questionnaires were sent to the attending physicians in all but 1 case. Up to date answers have been received from 38 of these and second samples were run on 14. Only one of these showed no reaction by the agglutination test.

There were 21 males and 17 females in the 38 cases in which more or less complete data are at hand. Of the 17 women, one was in the hospital for parturition, 3 had previously suffered from two or more abortions, and 1 was diagnosed as having uterine ulceration. These 5 cases are significant if Belyea's work on the infection of the genitourinary tract is considered.

The questions on the source and amount of the milk ingested were answered sufficiently for analysis in 29 of the 38 questionnaires. Eighteen of the persons who exhibited a strong reaction to the agglutination test had partaken of raw milk. Of these, 7 ingested cow's milk only occasionally, 5 partook of it in large quantities and 6 were moderate users. Only 5 of the cases used pasteurized milk and in 6, the source of the milk was unknown.

Of the remaining 10,094 samples, 103 showed a partial reaction in three or more dilutions, 94 in the 1-25 and 1-50 dilutions and 157 in the first or 1 - 25 tube only. No questionnaires were sent on these sample numbers because it was believed that many of these might be non-specific reactors.

Although in 5 cases blood cultures were made, the results were negative. It was impossible to follow most of these patients very far since only a few of them were in the hospitals, and many had left the care of the attending physicians before receipt of questionnaires.

DISCUSSION

The experimental data presented here must be considered as merely a preliminary report. It was designed to gain some idea, if possible, of the prevalence in the general population of persons whose sera reacted in fairly high dilutions to the agglutination test with *Bact. abortus* antigen. The fact that these sera were not selected but were taken as a matter of routine by some hospitals and also from patients for suspected syphilis gives some added significance to the results obtained.

There has been up to the present, no agreement as to the dilutions which are significant in indicating the presence of living *Bact. abortus* organisms in the human body. The dilutions employed in this work were merely empirical, and it is doubtful from the results obtained if the 1 - 25 and 1 - 50 dilutions give more than non-specific reactions. This is borne out by the fact that no blood cultures were obtained even in those reacting through the 1 - 100.

There are several possible explanations for the presence of agglutinins for *Bact. abortus* in human sera. First, the patients might be harboring an active focus of infection with *Bact. abortus* and the antibodies would be constantly formed under the stimulation of the growing bacterial antigen. In these cases, it would be expected that reactions to the agglutination test would be in fairly high dilutions and consistent. The persons themselves would either exhibit symptoms of undulant fever or they might remain normal as so often happens in carrier states in typhoid. Second, agglutinins might be present in large quantities in cases recently recovered from an active infection with *Bact. abortus*, but these reacting bodies would gradually disappear and the subsequent test should become weaker. Third, agglutinins for *Bact. abortus* are present in large quantities in the milks of some cows and persons ingesting these milks in moderate amounts might react to the test owing to the passive absorption of these reacting bodies into the blood stream. This last reaction would be transitory unless the milk drinking was continued over a long period. The fact that no positive blood cultures were obtained does not necessarily indicate that persons of the first class were absent in this survey inasmuch as one negative blood culture does not preclude the presence of *Bact. abortus* in an individual.

The results indicate that only about 0.6 per cent of the sera tested show a complete reaction in the 1 - 100 dilution. Of these, only a relatively small number showed any symptoms which simulated those of Malta fever. Approximately 1 per cent gave a partial reaction through the 1 - 75 dilutions and 1.5 per cent in the 1 - 25 dilution which may or may not have been specific in this case. Therefore, provided that the agglutination test has any significance, the number of persons in the general population infected with *Bact. abortus* must be relatively small. Hull and Black (1927) found approximately 7.3 per cent of the 69 patients who consistently gave negative Widal reactions but had characteristic fever symptoms reacted to dilutions of 1 - 200 or better by the *Bact. abortus* agglutination test. These samples, however, were selected because of certain symptoms and do not give an idea of the prevalence of the disease in the general population.

It is significant that from 29 questionnaires in which data were given on the source of the milk supply, that 18, or about 62 per cent of the reacting persons, were users of raw milk and only 18 per cent had ingested pasteurized milk. The source of the milk in 20 per cent of the cases was unknown and it is very probable that at least 50 per cent of these used raw milk. This fact should give an added reason for pasteurization of milk from tuberculosis free herds, but with the present

state of our knowledge on the value of the agglutination test and the relatively small numbers of the individuals involved as indicated by these results, it does not seem wise to enforce compulsory pasteurization of the products from abortion infected farms.

SUMMARY

1. Ten thousand, one hundred fifty-seven samples of human sera which were submitted for the Wassermann examination were tested by the agglutination reaction using *Bact. abortus* as the antigen. Of this number, approximately 0.6 per cent gave reactions up through the 1 - 100 dilution. These results obtained in a state where preliminary testing has shown at least 90 per cent of the dairy herds to be infected with *Bact. abortus* and approximately 60 per cent of the milk only is pasteurized, indicates that infection of man with the bovine type of *Bact. abortus* is relatively rare, provided any significance can be attached to the agglutination test.

2. Attempts to follow the small number of cases reacting through the 1 - 100 dilution by the agglutination test were made through questionnaires, subsequent testing and blood cultures. This method was unsatisfactory on the whole inasmuch as many of the patients remained under the care of the attending physicians for only a short time.

Measures Against Adenoids in Rome

AS a part of its campaign against adenoids, the government of the province of Rome established early in 1927 the first institute for the free treatment of adenoids. This institute is open to school children and young people. Soon after its establishment a special film on adenoids was prepared; it is loaned to private and public agencies. Later in the year circulars were sent out to the larger public child welfare agencies directing them to take measures for the treatment of adenoids among the children in their care. The National Bureau of Public Health is coöperating in this campaign by distributing literature on adenoids among the school teachers throughout Italy.—*Difesa Sociale*, Rome, Jan., 1928, p. 23.

The Age Distribution of Communicable Disease According to Size of Community*

EDWARD S. GODFREY, Jr., M.D., FELLOW A.P.H.A.

*Director, Division of Communicable Diseases, State Department of Health,
Albany, N. Y.*

THE lack of adequate tabulations of morbidity statistics in the United States has been felt probably by every worker in the field of practical epidemiology. For the most part, our knowledge of the prevalence, by age and sex, of the common communicable diseases rests upon hospital statistics, the published reports of a few city health departments, and occasional articles in professional journals. The neglect fully to utilize available morbidity data is in striking contrast to the work expended on mortality statistics with resulting enormous annual waste of collected material.

Morbidity reports are looked upon usually as being merely for the purpose of notification in order that the proper authority may take suitable action to prevent the immediate extension of the disease. It is not generally appreciated that they have a further value as a guide in devising or revising methods of control, and that they furnish a useful ground work for the intensive study of particular material under special conditions.

For the past seven years the Division of Communicable Diseases of the New York State Department of Health has been engaged in tabulating by age and sex, the morbidity and mortality for typhoid fever, scarlet fever, measles, whooping cough, diphtheria and poliomyelitis for the years subsequent to 1914. The tabulations show the gross morbidity, by small groups of communities classified according to population, and so far as good data were available, the age and sex incidence for each group, and according to the month in which the case was reported to the department. The deaths have been similarly classified except that they are given for the month in which they occurred. Unfortunately we have no data as to the age and sex incidence of these dis-

* Read at a Special Session on Preventive Medicine and Epidemiology, of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

eases in New York City or for cities of 20,000 and over, prior to 1918. Even since 1917, the reports from the cities of 200,000 to 1,000,000 have been so incomplete as to age and sex that their tabulation by these items was discontinued. We are now receiving, however, tabulated reports from the city of Buffalo, and in time these will afford a useful basis for comparison. The grouping of the various communities of the state according to their population was suggested by the material differences in the death rates of the urban and rural areas for the diseases under consideration as shown by mortality statistics from various sources, examples of which are shown in Table I.

TABLE I
AVERAGE URBAN AND RURAL DEATH RATES 1911-1920
REGISTRATION AREA AND NEW YORK STATE

	Typhoid		Measles		Scarlet Fever		Pertussis		Diphtheria	
	U	R	U	R	U	R	U	R	U	R

New York State	7.2	8.0	10.4	5.0	5.9	2.9	8.1	7.0	20.9	7.8

* Mortality Statistics, 1920 "Urban" = cities in registration states; "rural" = rural part of registration states.

Climatic and racial conditions, no doubt, constitute an important factor in the variations shown by federal statistics. For example, the urban population of the registration area is predominantly northern, the rural, southern and western. Diphtheria and scarlet fever ordinarily show higher death rates in the north than in the south and typhoid fever lower. Hence diphtheria and scarlet fever might easily be classified as an "urban" and typhoid as a "rural" disease without there really being anything more than climate as a causative factor. For the statistics of New York State, however, climatic differences are of little importance, and since in the main they correspond with the federal statistics so far as the diseases in Table I are concerned, it is to be inferred that there are essential differences between urban and rural communities which bring about this result. However, it was known, for example, that the favorable urban typhoid rates for New York State were due to the influence of the low New York City rates for this disease; that this New York City rate concealed an actually higher urban than rural rate in the remainder of the state. It seemed not unlikely therefore that within the broad classifications of "urban" and "rural" there also might be concealed conditions tending to high rates from communicable diseases whose recognition might enable us to concentrate our attack with better results for the effort expended.

Furthermore, the morbidity statistics formerly published by the Pennsylvania State Department of Health showed rather constant differences in the age distribution of urban and rural cases of scarlet fever and diphtheria, and it seemed desirable to ascertain whether these

variations held true for New York State for these diseases and also for measles, whooping cough and poliomyelitis, and whether these variations showed any constancy as the size of the community varied. Accordingly, the communities of the state were classified into 8 groups for the quinquennium 1915-1919 according to their estimated population as of July 1, 1917. The estimates for each group for each year were based on the United States census of 1910 and the state census of 1915. For the quinquennium, 1920-1924, the communities were grouped according to the estimated population of 1920 based on the state census of 1915 and the federal census of 1920.

Each of the groups is held constant for the quinquennium except as a village or city may be incorporated from previously unincorporated territory. In this event the population of the city or village is added to that of the group to which it belongs according to the enumerated or estimated population at the time of incorporation as shown by the return made to the secretary of state, and the same figure is subtracted from the population of the town group. We have preferred to keep the

groups thus constant throughout the quinquennium rather than shift the individual communities about from year to year as their estimated populations might rise above or fall below the limits of the group to which they were originally assigned. The principal reason for this was to avoid accidental fluctuations in rates due to epidemics. The division points are arbitrary in any event and there is no essential difference between a place of 2,400 and one of 2,600 or one of 9,000 and one of 11,000.

On the other hand the cyclical return of measles, for example, might strike a community the year of its transfer, or the year before its transfer to another group. In the former case there would be a purely artificial increase in the rate of the group to which the community was transferred while in the latter there would probably be factitious decrease because of the addition of a population with little likelihood of another outbreak for a number of years. Although it may be that the groups are too numerous, in that the populations of certain of them are too small and that essential differences between successive groups are not easily discernible, yet two or more groups may easily be combined by any one wishing a broader classification, as we do ourselves in common practice.

We have estimated also the populations for each 5-year age period under 20 and for the period 20 and over, for each of the population groups, and have calculated sundry items such as the percentage of foreign born women age 20 to 24, the number of families per dwelling, persons per dwelling and the percentage of illiterates. Unfortunately the federal census furnishes no figures which enable one to distinguish between incorporated places of less than 2,500 and unincorporated territory. There are other deficiencies in the figures on the characteristics of the population of places of less than 10,000 but this deficiency in the statistics of places of less than 2,500 population I regard as the most unfortunate. As will be seen from the subsequent tables there is a striking difference in the morbidity and mortality figures between incorporated places of less than 2,500 and the unincorporated towns. To what extent they are due to differences in the population makeup, we have no means of telling.

TYPHOID FEVER

The first of our tables to be considered is for typhoid fever, representing 33,597 cases and 4,653 deaths. The 10-year average of the case, death and fatality rates by each of the population groups is shown in Figure I. Both cases and deaths have been allocated to the place where infection occurred so far as this could be determined with reason-

FIGURE I

Case, death and fatality rates for typhoid fever according to size of community (density of population)
Average for New York State 1915-1924

able certainty. This shows quite distinctly that typhoid fever is neither a rural, nor a large city, nor yet a small village disease in New York. The highest case and death rates are in the cities of from 10,000 to 20,000. Both morbidity and mortality regularly increase through the successive groups to this group and then decline. The inferences we draw from the table are that rural conditions in New York are not very favorable to the transmission of typhoid fever; that flies play a minor rôle, that the infection of private wells is not very common; and that contact cannot be a major factor else the rate would continue to increase as dispersion decreased.

The high rates in places of from 5,000 to 20,000 indicate inadequate safeguards over the water and milk supplies. A well that may supply without mishap a community of 5,000, begins to drain pollution when twice as much water is pumped from it or an auxiliary supply of doubtful purity is resorted to from time to time as the regular supply fails. The need for a better quality of supervision than suffices for the small village is not recognized. This failing is even more likely to be true of the milk supply. The personnel of the health department is not expanded to keep pace with the increasing number of dairies, and pasteurization of the milk supply encounters greater difficulties than in larger places.

Personally, I believe that a very large part of this small city typhoid is transmitted through milk and water and remains unrecognized as such because the cases occur sporadically or in very small outbreaks, the primary epidemiological data are not collected with sufficient thoroughness, and the histories of cases of prior years are not reviewed with those of the current cases.

TABLE III
PERCENTAGE OF TOTAL CASES AND DEATHS AND FATALITY RATE AT EACH AGE PERIOD
ALL PLACES UNDER 200,000 POPULATION, 1915-1924

Age	Per cent of all ages		Fatality Rate Per cent

50-54	3.3	6.1	22.9
55-59	2.0	3.7	22.8
60 and over	2.9	8.7	36.5

Despite the low rates in the unincorporated towns and the small villages, it is a common custom of the larger places to charge their summer and autumnal typhoid increase to vacations in the rural districts. Failure to study local cases honestly has led to at least one disastrous outbreak in recent years.

The average distribution of cases and deaths and the fatality rates by age of typhoid are shown in Table III, representing 16,607 cases and 2,034 deaths. The largest number of cases was in the age period 10 to 14 years with the period 15 to 19 years almost as large. Of all the cases, 28.5 per cent fall in the period covering the second decade of life. The largest number of deaths occur from 20 to 24 years, the 15- to 19-year period again being a close second. There is little difference in the proportion of cases by ages between the smaller and larger communities except that a much larger percentage of the cases and deaths occur at 60 and over in the places under 10,000, than in places of greater size. The lowest fatality rate is at age 5 to 9, when it is about one-third of the rate at all ages. The fatality rate at all ages over 45 is very high, but only a little over 12 per cent of the cases occur after that age.

DIPHTHERIA

The case, death and fatality rates for diphtheria by size of place are shown in Figure II, representing 200,111 cases and 16,030 deaths. It will be observed that there is a fairly uniform decline in both the case and death rates as we go from the largest cities to the smallest villages and that although the morbidity rate is less in the towns than else-

FIGURE II

Case, death and fatality rates for diphtheria according to size of community (density of population)
Average for New York State 1915-1924

where, the mortality is higher than in the small village group. The fatality rate is highest in the towns, next highest in the largest cities, and is lowest in the small villages.

Two exceptions to these general statements are to be noted: First, the case and death rates for New York City are smaller than the corresponding rates for places from 200,000 to 1,000,000; and, second, the rates for places of 20,000 to 50,000 are smaller than the rates for those of 10,000 to 20,000. As to the first, an examination of the annual figures show that for the first 5 years of the decennium, the rates were almost identical and that the New York City rate fell very rapidly after 1919.

The rate in the group of 200,000 to 1,000,000 also began a very rapid decline after 1920 but this was largely a recession from a period of very high rates due to an extensive and very fatal outbreak in Buffalo. The New York City decline therefore seems more significant of improvement in control. In 1921 the rate for that city was lower than for the rest of the state for the first and only time in its history, following two years of extensive toxin-antitoxin work that had been done in the public schools by the late Dr. Zingher. It seems possible that although this school immunization did not reach the heart of the problem, it made possible an unprecedented reduction from the rates of former years.

We are unable to account for the unusually low rate in places of 20,000 to 50,000. This same discrepancy appears also in the case rates from scarlet fever and the death rates from scarlet fever and measles. We have sought rather diligently for a plausible reason, but apparently it is not to be found in the population makeup, nor can it be

accounted for by notable work in immunization, since much the same irregularity existed for the 5-year period 1915-1919 before any large scale toxin-antitoxin work was begun. The outstanding fact, as shown by these figures, is that diphtheria is a disease of cities both in prevalence and mortality—a fact more clearly shown when we compare the case and death rates of places over, and places under 10,000 (Figure III).

FIGURE III

The lower case rate and the higher death rate in the unincorporated territory has been noted. This is a feature which is also common to scarlet fever, measles and whooping cough, but not as we have already seen to typhoid fever, nor as we shall see later to poliomyelitis. We have interpreted this as being due partly to poor reporting in the unincorporated districts and partly to less adequate medical and nursing care. We have not attempted to assess the relative weights of these two factors as it is obviously difficult to obtain the data necessary to form a judgment. It is not unreasonable to believe, however, that considering the distances to be covered, the greater expense and the difficulties of winter travel in New York State, the administration of antitoxin is frequently delayed in rural districts either because the physician is not called until the case is regarded as serious or because an extra trip has to be made if the physician is not given a hint as to the possibility of diphtheria before making his first visit. The likelihood of death from respiratory obstruction before medical aid can reach the patient is also increased.

The age distribution of diphtheria cases and deaths and the fatality rates by age are shown in Table IV, representing 50,256 cases and 3,715 deaths. It will be seen that a little less than a quarter of all the cases and a little more than half of the deaths occur in the first 5 years of life; that a little more than a third of the cases and rather less than a third of the deaths occur in the age period 5 to 9. The table shows that 57 per cent of the cases and 82 per cent of the deaths occur in children under 10 years of age. The importance of this in planning a toxin-antitoxin campaign is quite apparent. Where the resources are limited and the difficulties at best are very great, it is extremely important

TABLE IV

PER CENT OF TOTAL CASES AND DEATHS AND FATALITY RATE AT EACH AGE,
ALL PLACES UNDER 200,000 POPULATION, 1915-24

Diphtheria

Age	Per cent of all ages		Fatality Rate Per cent

15-19	7.0	2.4	2.5
20 and over	18.3	6.9	2.9

that the efforts be expended where they will produce the greatest corresponding benefit. The failure to reach the preschool age group means that less than half of the mortality can be prevented at the most, and that campaigns limited to school children will not suffice to reduce the death rate permanently to a very marked degree.

In Table V are shown the percentages of cases and deaths under 5 years of age according to the size of the community. This is interesting in that it shows the much higher proportion both of cases and deaths at this age in the large communities as compared with the small ones, a feature common to this class of diseases. It will be noted that in the group of 20,000 to 50,000 population the percentage of deaths is very much smaller than in the three succeeding groups. A somewhat surpris-

TABLE V

2,500-5,000	19.8	50.5	18.1
Under 2,500	13.9	37.0	16.7
Unincorporated	19.1	46.2	20.5

ing figure is the large percentage of cases and deaths under 5 years of age in the unincorporated territory, much larger it will be noted than in the group of smallest villages. The fatality rates at this age are shown in column 3 and call attention to the very high rate which still prevails despite the almost universal use of antitoxin.

Since it is quite obvious that the age distribution of the population may be responsible for certain of the variations in the incidence at different age periods, Table VI shows the specific case and death rates

TABLE VI

AVERAGE CASE AND DEATH RATES PER 100,000 POPULATION AT EACH AGE PERIOD 1915-24

Diphtheria

All others	176	35	300	24	187	8.5	105	3.1	31.8	1.2

by 5-year age groups under 20 years. It is unfortunate that we are unable to give separate rates for the small villages and the unincorporated territory as it may be that there are important differences. It will be noted that the recession in case and death rates in the cities of 20,000 to 50,000 previously mentioned holds in the specific as well as in the crude rates. It will be seen too that the decline in the case and death rates from those of large places to those of small is most marked in the lower age periods.

MEASLES

The distribution of measles cases and deaths and the fatality rates by size of the community are shown in Figure IV, representing 594,159 cases and 8,176 deaths. For places other than New York City the deaths occurring in institutions for children have been excluded. The high fatality rates which formerly at least prevailed in these institutions produced an undesirable distortion of the mortality and fatality rates; in other words, the fatality and mortality rate of a group would depend in a considerable degree upon whether or not there were located in the communities constituting that group a number of institutions caring for small children. The unequal distribution of such institution deaths is shown by the fact that in the places of 200,000 to 1,000,000, only 5 of the 557 deaths in the 10-year period were in such institutions, whereas in places of 50,000 to 200,000, 85 out of 654 deaths occurred

FIGURE IV

in such institutions. In the one case the mortality rate per 100,000 population was raised by only 0.1 and in the latter by 1.2.

The noticeable feature of the case rate is that measles was apparently equally as prevalent in the smallest villages as in the cities, although the mortality rate shows much the same tendency to decline that we found in diphtheria.

Attention is called to the extremely low fatality rate for the small villages where out of 31,214 cases there were but 120 deaths in the 10-year period.

The per cent of cases and deaths and the fatality rates by age are shown in Table VII, representing 268,250 cases and 1,940 deaths. It will be observed that although only 13.2 per cent of the cases occurred in children under 3 years of age, that 66.4 per cent of all of the deaths occurred at those ages. Seventy-five and one-half per cent of the deaths occurred under 5 years of age, and although nearly 50 per cent of the cases occurred from the 5th to the 14th year these age periods were responsible for only 12 per cent of the deaths. The highest fatality rate was in children under 1 year of age but the greatest number of deaths occurred at age 1 year. The fatality rate drops very rapidly during the first few years of life and the disease is apparently least fatal between the 5th and the 15th year.

There is some question, of course, as to the relative completeness of reporting at the different ages, as it might be that a child of school age would have a better chance of being reported than the preschool child or the adult. We have endeavored to answer this question from the data secured during the intensive investigations of a few community epidemics, and find that although in an epidemic in a small village the

TABLE VII
PER CENT OF TOTAL CASES AND DEATHS AND FATALITY RATE AT EACH AGE, ALL PLACES
UNDER 200,000 POPULATION, 1915-1924

<i>Measles</i>			
Per cent of all ages			Fatality Rate Per cent
Age	Cases	Deaths	
Under 1 year	2.2	24.6	7.93
1	4.8	30.8	4.63
2	6.2	11.0	1.29
3	7.0	5.7	0.59
4	7.7	3.4	0.32
5	9.1	2.5	0.20

5-9	43.9	9.2	0.15
10-14	14.8	2.8	0.14
15-19	6.2	2.6	0.30
20 and over	7.2	9.9	1.00

reporting was actually better in children under 5, the reverse has been true in each of the larger places. In a city of 20,000 the ratio of completeness of reporting was about 9 to 10 and in two cities of over 100,000 the ratio was about 7½ to 10. These investigations have also shown that the ratio of reporting was much less complete in the larger places than in the smaller ones, accounting in part for the relatively lower case rates and higher fatality rates in the former.

TABLE VIII
AVERAGE CASE AND DEATH RATES PER 100,000 POPULATION AT EACH AGE PERIOD 1915-24

Population Group	<i>Measles</i>									
	Under 5		5-9		10-14		15-19		20 & over	
	C	D	C	D	C	D	C	D	C	D

2,500-5,000	2742	41	4710	8.5	1303	0.8	455	1.6	69.2	0.5
All others	1551	29	2615	4.1	1507	2.3	887	2.9	110.0	1.2

Table VIII shows the specific rates by age. The high mortality in children under 5 years old and the comparatively low death rate at this age in places of from 20,000 to 50,000 are noteworthy. The low case and death rates under 5 years and the higher case and death rates in the age groups over 10 in places of less than 2,500 indicate cause and effect in herd susceptibility.

WHOOPIING COUGH

Figure V shows the distribution of whooping cough cases and deaths and the fatality rates by size of the community, representing 168,315 cases and 7,353 deaths. It will be noted that although the case rate is

FIGURE V

Case, death and fatality rates for whooping cough according to size of community (density of population)
Average for New York State 1915-1924

more than twice as high in the state outside of New York City as in the city itself, the death rates are practically identical. Less complete reporting undoubtedly accounts for the bulk of this discrepancy.

There seems to be no regular relationship between either the morbidity or mortality rates and the size of the community. I would point out, however, that although whooping cough is frequently spoken of as a rural disease and the death rates for the registration area show a higher mortality in the urban than in the rural districts, in New York State the highest morbidity and highest mortality are found in the two groups comprised of places having populations of from 10,000 to 50,000. The fatality rates are highest in the larger cities, lowest in

TABLE IX

PER CENT OF TOTAL CASES AND DEATHS AND FATALITY RATE AT EACH AGE, ALL PLACES
UNDER 200,000 POPULATION, 1915-1924

Whooping Cough			
Per cent of all ages			Fatality Rate
Age	Cases	Deaths	Percent
Under 1 year	7.9	56.9	20.07
1	8.1	23.1	7.96
2	9.7	7.9	2.29
3	10.6	3.6	0.95
4	10.5	2.5	0.66
5	11.0	1.4	0.36
6	10.9	1.0	0.26
7	8.7	0.9	0.28
8	6.5	0.5	0.23
9	4.1	0.2	0.14
Under 5 years	46.8	94.1	5.62
5-9	41.2	4.0	0.27
10-14	8.5	0.6	0.20
15-19	1.4	0.3	0.58
20 and over	2.1	1.0	1.33

the small villages and apparently depend for the most part on the relative completeness of reporting.

The age distribution of the cases and deaths and the fatality rates by age are shown in Table IX and serves to emphasize the large proportion of deaths which occur in the early years of life, especially during the first year of life. Nearly 95 per cent of all the deaths occur at this time. It also shows that unlike measles the greatest morbidity is during this age period.

TABLE X

AVERAGE CASE AND DEATH RATES PER 100,000 POPULATION AT EACH AGE PERIOD, 1915-24
Whooping Cough

Population Group	Under 5		5-9		10-14		15-19		20 & over	
	C	D	C	D	C	D	C	D	C	D
50-200,000	945	51	777	1.4	90	0.2	10	0.0	4.6	0.04
20,-50,000	1298	51	1075	2.2	123	0.0	15	0.0	5.1	0.00
10,-20,000	1543	90	1190	3.1	132	0.3	21	0.0	6.3	0.04
5,-10,000	948	59	862	4.1	121	0.0	17	0.0	3.3	0.13
2,500-5,000	1448	72	1277	2.7	179	1.6	28	0.0	7.7	0.11
All others	964	61	952	3.0	310	0.5	65	0.5	8.6	0.14

The specific case and death rates by age are given in Table X. With the exception of two groups the death rate under 5 is higher than for any other of the so-called children's diseases and the death rates at this age are higher in each of the groups under 10,000 population than in either of the two groups of over 20,000. This is a remarkable thing in a disease of the respiratory tract presumably transmitted by immediate contact. It is important because it seems to support the hypothesis that poliomyelitis is ordinarily transmitted in much the same way.

Whooping cough ranks next to diphtheria in New York as a cause of death from the acute communicable diseases of childhood and its death rate has declined less than that of any of the others during the past twenty years. It is the least completely reported and is perhaps the most difficult to control of our epidemic diseases.

POLIOMYELITIS

The case and death rates and the fatality rates for poliomyelitis by size of community are shown in Figure VI, representing 18,299 cases and 4,337 deaths. The relatively high case and death rates in New York City are due entirely to the great epidemic of 1916. Since then the highest case rate in New York City has been 10 per 100,000 and the highest death rate 2.5 per 100,000. Most of the other groups shared in the high rates of 1916 but the places of 200,000 to 1,000,000 were an exception. It is a curious fact that the city of Rochester has never suffered a large epidemic of poliomyelitis.

The remarkable feature in the distribution of poliomyelitis by size

FIGURE VI

POLIOMYELITIS

Case, death and fatality rates for poliomyelitis according to size of community (density of population)
Average for New York State 1915-1924

of community is the high case and death rate which prevailed in places of less than 5,000 population. I wish to point out also that the case rate, as well as the death rate, was higher in the unincorporated towns than in the groups of denser population, and the fatality rate was lower than in the villages of less than 2,500. It seems to me that this distribution is very difficult to explain on the hypothesis that poliomyelitis is spread for the most part by contact and through the secretions of the nose and throat. None of the other diseases supposed to be so transmitted shows a higher crude case rate in places where the dispersion of population is greatest and the mortality and fatality rates seem to confute the argument that it is due to vagaries of reporting.

TABLE XI

PERCENTAGE OF TOTAL CASES AND DEATHS AND FATALITY RATE AT EACH AGE, ALL PLACES
UNDER 200,000 POPULATION, 1920-1924

<i>Poliomyelitis</i>			
Age	Per cent of all ages		Fatality Rate
	Cases	Deaths	Per cent
Under 1 year	4.3	6.8	26.1
1	10.1	10.8	17.4
2	10.8	6.5	9.8
3	9.0	5.7	10.3
4	8.3	6.8	13.4
5	5.8	4.5	12.8
6	6.2	4.0	10.4
7	4.8	5.1	17.3
8	3.8	3.4	14.5
9	3.6	2.6	11.7
Under 5 years	42.5	36.6	14.0
5-9	24.2	19.6	13.2
10-14	15.0	17.3	18.9
15-19	8.7	7.7	14.4
20 and over	9.6	18.8	31.7

The distribution of cases by age, shown in Table XI, shows that less than half of the cases and deaths occurred in children under 5. It also shows that nearly 10 per cent of the cases and almost 20 per cent of the deaths occur in adults. The percentage of cases for each age group by size of community shows the usual greater incidence among the young in the larger places and the relatively large distribution among adults in the small villages and unincorporated towns. The number of cases comprised in some of the groups as shown is quite small, however, and one's interpretation must be cautious.

TABLE XII
AVERAGE RATES PER 100,000 POPULATION AT EACH AGE, 1920-24
(BASED ON 1922 POPULATION ESTIMATES)

Population Group	<i>Poliomyelitis</i>									
	Under 5		5-9		10-14		15-19		20 & over	
	C	D	C	D	C	D	C	D	C	D
50,-200,000	63	5.2	27	3.0	12	3.5	7	2.8	1.0	0.3
20,-50,000	54	9.2	22	2.1	10	2.7	8	1.9	1.3	0.3
10,-20,000	44	7.4	26	4.3	18	2.9	14	1.2	1.5	0.6
5,-10,000	32	4.8	14	4.0	10	2.2	5	0.0	0.6	0.0
2,500-5,000	46	6.7	25	2.3	15	3.1	10	0.9	0.9	0.1
All others	43	6.8	32	4.4	23	3.8	16	1.7	2.1	0.7

Table XII shows the specific case and death rates by 5-year age groups. The comparatively high case and death rates in places over 10,000 as compared with smaller places of ages under 5 is in contrast with the crude case and death rates. The comparatively low case and death rates at all ages in places of 2,500 to 10,000 and the high case and death rates, especially the former, in places under 2,500, are perhaps worthy of remark.

In the foregoing I have selected certain features shown by the tables and touched briefly upon my interpretation of them. But whether the selection is good or the interpretation is correct is of less importance than bringing these tables and the more extended ones upon which they are based* to the notice of others better able to deal with them from a technical standpoint. We know that they have an immediate value in administrative practice and they have suggested hypotheses we hope to test by further investigations. I feel quite sure that there are implications which have altogether escaped me but which will be discovered by other more discerning workers. It is not too much to hope, I trust, that good use will be made of these figures, that other lines of investigation will be suggested, that our knowledge of communicable diseases will be to some extent deepened and administrative procedure placed on a sounder basis.

THE PREVALENCE OF THE VENEREAL DISEASES

HOW much syphilis and gonorrhea is there in the United States? Accurate data on the prevalence of the venereal diseases are lacking. Old figures are still being quoted, such as those obtained from the draft examination, special group reports, such as army, navy or hospital figures, and case reports made to state health departments and collected by the U. S. Public Health Service. It has been impracticable so far to obtain accurate information for a general population group. Such information is essential to an intelligent understanding of the many problems connected with the control of the venereal diseases. Therefore, an effort has recently been initiated to take soundings in various parts of the country—that is, to select cities typical of various conditions and make every possible effort to obtain a count of “known” cases of syphilis and gonococcal infection.

To answer, then, the question, “How much syphilis and gonorrhea is there in the United States?” incidence studies have been made by the American Social Hygiene Association in coöperation with the U. S. Public Health Service in a number of places including Detroit, Atlanta, Cleveland, New Haven and other cities and counties. The desired information was secured through personal interviews of doctors and other persons “licensed to practice the healing art.” Each one was asked how many cases he had under treatment or observation on a given date. The accuracy and completeness of the data was entirely dependent upon the physicians’ good faith and willingness to coöperate in the undertaking. Interest was shown to a surprising degree, and there has been a general request for final tabulated results. In Detroit only 8 out of 1747 practitioners refused information.

Of the 1,739 physicians who did reply in the Detroit study 49 per cent reported one or more cases of venereal diseases. Of the 66 clinics and hospitals reporting, 35 per cent had cases under treatment. In

all, 16,735 cases of syphilis and gonorrhea were said to be under observation or treatment on the day selected, a rate of 13.47 cases per 1,000 total population of the city. Males over 16 years of age showed a rate of 24.29 per 1,000 of the corresponding group of the population. Of the total cases reported, 8,665 were syphilis, a rate of 6.98 cases per 1,000 population, and 8,070 were gonorrhea, or 6.50 per 1,000. Of the total number enumerated, syphilis cases were slightly more numerous than gonorrhea cases, but in the male group 16 years and over, gonorrhea cases slightly predominated. Seventy per cent of the total number were being treated in private practice. About 96 per cent of the total number of cases were among persons 16 years of age or over, but among males about 97 per cent of the cases and among females 91 per cent were of this age group. Relatively more cases seem to occur at the younger ages among females. Of the total number of syphilis cases, 37 per cent were females, and of the total gonorrhea cases 22 per cent. But among persons under 16 years of age 52 per cent of syphilis cases and 72 per cent of the gonorrhea cases were among females. It appears that both of these diseases are relatively more frequent among young females than among young males.

The question arises as to what is the relation of the number of cases under treatment or observation on one day to the total number seen in a year. Accordingly many doctors were questioned as to the annual turnover of patients in their offices. Estimates varied between 5 and 20. Many patients "shop around" between different doctors and clinics during the course of a year so that if a year's cases were counted there would be considerable duplication of individuals. The clinic probably makes a greater effort than the private physician to keep its patients continually coming for treatment until cured. So taking everything into consideration, it might be assumed that the patients enumerated in the one day census were about one-fifth of the total number seen in a year.

The information collected by the Detroit survey and other similar studies cannot possibly give an accurate measure of the actual prevalence of venereal diseases. Even if cases known to medical practitioners can be counted accurately, there is no way, from the information now available, in which the number of cases can be estimated which are not under treatment, either on account of ignorance or indifference of those affected, or because they are undergoing self-treatment. The count in the Detroit survey, however, revealed an unexpected number of cases actually under treatment. How many more there must be it is impossible to say. The army figures showed a ratio of one syphilis case to every four of gonorrhea. The Detroit study showed gonococcal

infections, among males over 16 years of age at least, only slightly outnumbering syphilis cases. Does this mean that there is less gonorrhea among adult men than was found at the time of the army draft examination ten years ago, or is self-treatment or no treatment at all a common state of affairs, so that a large number of existing cases were not counted in the Detroit study? These and other questions of a similar nature are important to the public health administrator today.

Another important fact brought out by the survey was that 70 per cent of all the cases enumerated were under treatment by private practitioners. About half the physicians visited had cases under treatment. Thus it would seem that the physician, rather than the public clinic, very largely holds in his hands the problem of the control, and therefore the prevention, of the venereal diseases.

These studies will be continued, and it is hoped that by the end of 1928 enough data will be in hand to provide a base line from which to measure future trends in venereal disease incidence.

NOTE Copies of the report *A Survey of the Venereal Disease Prevalence in Detroit*, can be had upon application to the American Social Hygiene Association, 370 Seventh Avenue, New York, N. Y.

THE FOOD VALUE OF MILK

WE believe that there is no question in the minds of American physicians concerning the necessity of milk as a food, especially for growing children, though its value for adults is also recognized. The general knowledge of the food value of milk was recognized long before the discovery of vitamins. This discovery, however, added exactness to our observations and strength to the argument in favor of milk.

Recent publications of a preliminary report^{1,2} made under the auspices of the Scottish Board of Health have confirmed the previously held ideas and carried them somewhat further. Groups of children of the ages of 5 to 6, 8 to 9, and 13 to 14 years in seven Scottish towns were selected, four groups for each town, each of which contained from 40 to 50 children. The first group was given the ordinary diet; for the second the diet was supplemented by biscuit, the third by separated milk, and the fourth by whole milk. The feeding was carefully superintended at the schools, in addition to which, the home dietary in 626 cases was studied, since some children received milk there in addition to that given at the schools, and the latter was regarded as an accessory article of diet. The experiment continued over seven months, and showed an average monthly increase of 0.17 inches and 0.42 pounds for the groups which did not receive extra milk, against 0.21 inches and 0.52 pounds for those receiving milk. The average increase in height was 1.470 inches, and in weight 3.617 pounds, for the milk-taking

group, against 1.212 inches and 2.974 pounds for those not receiving it. These figures include the three age groups mentioned. For the age group 5 to 6, the percentage of increase in height of those taking over the average amount of milk was 9.4, for the age group 8 to 9, 15.5, and for the 13 to 14 group, 24.2.

The general condition of the children was noted, and on the whole it was found that the hair was glossier, the complexion clearer, and they held themselves more erect. There were some exceptions to this general rule, and the most marked improvement occurred in those groups in which the condition of the children was poorer to begin with. The general condition, however, has led Dr. Orr, who is Chairman of the Research Committee, to draw conclusions which he calls provisional, though there is little doubt that further experiments which are under way will confirm them. These may be summed up as follows:

The children who received an addition of milk to their diet showed a rate of growth as indicated in both height and weight, 20 per cent greater than those not receiving the extra milk, accompanied by an improvement in their general condition. Of particular interest are the groups which were fed on separated milk, which has been discredited in this country as well as in England to a great extent. Dr. Orr concludes that it is of great value for promoting growth and that its nutritive value seems to have been much underestimated. The *British Medical Journal* makes the interesting comment, in comparing the children fed on biscuit with those taking extra milk, that the aggressive and dominant races have usually been those which consumed milk, while the docile and subject ones have used grain as their principal diet.

While accepting these conclusions, concerning the accuracy of which we have no doubt, we wish to point out that there is no food of equal value which is generally so badly handled as milk, or which has been subject to so great manipulation. In most countries, especially the United States and England, there are numerous regulations concerning the quality and handling of milk and milk products, and one need only consult the records to see how often these regulations are violated.

Milk varies with the season and with the feeding of the cow, especially in regard to its vitamin content. Campaigns to increase the drinking of milk and the use of butter are excellent in their way, but the public deserves to have the information that there is a great difference between the milk derived from pasture-fed cattle and that obtained in winter from stall-fed animals, unless particular attention is paid to their diet, and that dirty milk is a menace rather than a blessing.

ASSOCIATION NEWS

*The New Field Museum of Natural History
Roosevelt Road in Grant Park*

57TH ANNUAL MEETING OF THE A.P.H.A.

CHICAGO and the Middle West are eagerly looking forward to the 57th Annual Meeting to be held at Hotel Stevens, October 15-19. The Local Committee has been organized under the chairmanship of Dr. Louis E. Schmidt, and plans are being made in coöperation with the Association officers for the largest meeting we have ever had.

The last Annual Meeting in Chicago was held in 1918. While a successful one in many ways, it was held under disadvantages as the man power and energies of the nation were then directed toward one thing—success in war. Chicago has made wonderful strides in the last decade, not only in public health achievements but also in civic developments. The delegate to the 1918 meeting who has not been in that city since will experience a most agreeable surprise when he returns to Chicago this fall. He will find an entirely new skyline always in a state of change; a new and growing lake front park system, made by filling in Lake Michigan, beautified by magnificent buildings and

monuments; spacious single and double-decked boulevards for the building of which whole city blocks were wrecked; improved railway terminal facilities, and an atmosphere of enthusiasm locally, which is equally as contagious as it is invigorating.

Chicago has truly won the unique distinction of being the Convention City of America. It has an abundance of the things which go to make a success of a meeting such as the American Public Health Association sponsors—where the delegates come to spend a week in seriously applying themselves to professional matters relating to public health, but where they are afforded relaxation in profitable entertainment. To this end the Chicago Local Committee is formulating its policies and directing its efforts.

The selection of Hotel Stevens as headquarters assures the best in the way of convention service. This hotel is the largest in the world, having over 3,000 guest rooms. It can not only accommodate all delegates and guests, but house

Municipal Pier

all convention activities under the one roof—meetings, exhibits, and entertainment features.

The Stevens is Chicago's newest hotel and is splendidly located with reference to railroad terminals and local transportation facilities. It is on Michigan Boulevard, famous the world over for its fashionable shops and brisk lake breezes, and overlooks Grant Park and Lake Michigan. This park holds the keystone position in Chicago's lake front park system and is being developed as one of the most elaborate and magnificent civic centers in the world. From his room in Hotel Stevens, one may look across the park and see the beautiful Buckingham Memorial Fountain with its gorgeous display of graceful water sprays. This fountain in display at night is a real inspiration. To the south stands the famous Marshall Field Museum of Natural History, one of the finest specimens of Grecian architecture on the continent, and costing over \$7,500,000. Within this museum are acres of exhibit rooms where are shown thousands of

priceless collections and rare specimens. Its collections of anthropological, botanical, geological and zoological exhibits rate with the world's best. Here may be seen some of the finest taxidermy and the finest collection of jewels in America. The visitor could spend weeks in this museum and still have much to see and learn. The directors of this institution have dispatched scores of scientific expeditions to all parts of the world collecting specimens, making new discoveries and seeking additional facts in many fields of natural history.

Soldiers' Field with its huge stadium is situated just south of the museum and harmonizes with it in architectural features. Here were held the famous Army-Navy football game of 1926, the great Tunney-Dempsey fight and the World's Eucharistic Congress of 1927. The stadium has seated as many as 150,000 people.

Beyond the park and extending eastward to the skyline at the horizon lies Lake Michigan. Projecting out of the water like tiny islands and sometimes

Soldiers' Field

mistaken for vessels may be seen the circular crib structures protecting Chicago's water works intakes. A little to the north one sees the Municipal Pier extending out into Lake Michigan nearly a mile. This structure is one of the

drive north through Lincoln Park is one of the most beautiful boulevards in America. Lincoln Park with its charming lagoons and quaint by-ways, its flower conservatory, zoölogical garden, athletic grounds, yacht harbor, bathing

Buckingham Memorial Fountain in full play

most modern of its kind. It serves as the docking terminal for the fleet of freight and passenger vessels which operate out of Chicago, and at the extreme end has a spacious recreational center where hundreds of Chicago families spend the hot summer days in the comfort of fresh lake breezes. Up Michigan Boulevard a few blocks are the Art Museum, the Public Library and the statue group, "The Spirit of the Great Lakes." The former ranks among the best art galleries in the country, containing excellent examples of old masters and modern paintings and a collection of sculpture both ancient and modern.

The Local Committee will make ample provisions for our members to see Chicago. The thirty miles of boulevards connecting up Chicago's park system makes an auto trip about the city a real pleasure. Chicagoans love and make real use of their parks. The lake shore

beaches, public golf course, and rifle range is a real playground for young and old, as well as a beauty spot such as few cities possess.

The wide south side boulevards which begin at Grant Park, pass by Field Museum and Soldiers' Field along the lake front, and lead to Washington and Jackson Parks—The latter was the site of the World's Fair over a third of a century ago. Connecting these two parks is the famous Midway of the fair days, now part of the boulevard system, on the north side of which are clustered the buildings of the University of Chicago. The new Medical School and the chapel are imposing additions to the university buildings group. Jackson Park is the largest of the city's parks. On its Japanese Island of the World's Fair days still stands Cahokia Court House, the oldest public building in the Mississippi Valley. The public bathing

beach, the golf grounds, tennis courts and yacht harbor offer splendid recreational facilities. Washington Park is known for its numerous athletic grounds, its flower conservatory with sunken gardens, and Lorado Taft's famous statue, the "Fountain of Time" at the west end of the Midway. On the west side Columbus, Douglas, Garfield and Humbolt Parks rival in beauty and public service those parks located on the lake front. They are all interconnected by boulevards and are notable for their beauty as well as their recreational facilities. The flower conservatories in Garfield Park are as beautiful as any in America. The seasonal flower shows held there attract national attention.

The public health activities in Chicago are many and varied. The local committee will arrange for the proper introduction of delegates and admission to places of interest. The health officers will find Chicago's Health Department activities a model of efficiency and service. Research workers in medicine and public health will be given the opportunity to see much of the work of their professional colleagues at such institutions as the Chicago, Northwestern and

Loyola Universities, the School of Medicine of the University of Illinois, and the McCormick Institute of Infectious Diseases. The Chicago Hospital clinics and Welfare stations will welcome our members. The public health engineers have offered them a wealth of interesting things to see in the activities of the Chicago Water Works, the Sanitary District of Chicago, and the milk and ventilation control work of the Health Department. The industrial hygienists will find much of interest to them in the great plants in the Chicago region, such as the Stock Yards, Western Electric Company, International Harvester Company, the Pullman Company, and the steel mills. The public health nursing activities, including welfare work, is splendidly organized in Chicago and Cook County. The public health group members in the Illinois District Nurses section are planning big things for the A. P. H. A. meeting this fall.

The Chicago meeting, in bringing together the representative public health workers of this continent, should be the high-water mark in the advance of the public health movement and begin a new era in the affairs of our Association.

A. P. H. A. AIDS CHAUTAUQUAS

The Association is coöperating with the Redpath and Swarthmore Chautauquas and the Milbank Memorial Fund in a program of public health education. This project is under the direction of the Committee of which S. J. Crumbine, M.D., is chairman. Lectures on public health and personal hygiene will be given under Chautauqua auspices in 291 small cities and towns in 14 north-eastern states. Edward T. Devine, M.D., who has been temporarily engaged by the Association to assist in the project is working in close coöperation with the official health authorities and voluntary agencies in the states concerned.

DR. DEACON IN TEXAS

W. J. V. Deacon, M.D., of the Michigan State Health Department has been temporarily loaned to the Association for service under the direction of the Committee on Registration Area. Dr. Deacon is now in Texas with the State Department of Health to assist it in entering the registration area.

PARKER BILL PROGRESS

The Parker Bill, which provides for correlation of federal health services, with minor changes has passed the Senate. These changes must be agreed to by the House of Representatives.

REGIONAL MEETING IN PORTLAND, ORE., JUNE 18

PLANs for the first regional meeting of the Association are rapidly taking shape under the direction of William C. Hassler, M.D., *Chairman* of the Temporary Organizing Committee for the West.

The other members of this committee are: E. T. Hanley, M.D., Vice-Chairman; John J. Sippy, M.D., Secretary; J. L. Pomeroy, M.D.; George Parrish, M.D.; James J. Waring, M.D.; Robert A. Peers, M.D.; H. B. Hommon; William P. Shepard, M.D.; H. E. Young, M.D.; F. D. Stricker, M.D.; and W. F. Cogswell, M.D.

The meeting will be held in Portland, Ore., on June 18. The program calls for a full day's session with a round table luncheon and an evening meeting. All members of the Association are invited to attend the meeting and to participate in the discussion.

The tentative program will include the following:

1. The Organization Objectives of the Western Branch. WILLIAM C. HASSLER, M.D., San Francisco, Calif.

Discussion, E. T. HANLEY, M.D., Seattle, Wash.

2. Effect on Native Population of Immigration of Physical Defectives. JAMES J. WARING, M.D., Denver, Colo.

Discussion, JOHN G. ABELE, M.D., Portland, Ore.

3. Is the Filipino a Menace from the Public Health Standpoint, and Should He Be Examined at the Point of Embarkation? F. D. STRICKER, M.D., Portland, Ore.

Discussion, DONALD J. FRICK, M.D., Los Angeles, Calif.

4. The Value of Health Centers. J. L. POMEROY, M.D., Los Angeles, Calif.

Discussion, WILLIAM DEKLEINE, M.D., Salem, Ore.

5. The Spread of Communicable Diseases from Transient Mexican Labor. GEORGE PARRISH, M.D., Los Angeles, Calif.

Discussion, JOHN J. SIPPY, M.D., Stockton, Calif.

6. How to Put Community Health Surveys to Work. W. F. WALKER, Dr. P. H., New York, N. Y.

The National Tuberculosis Association will hold its regular annual meeting in Portland during the week of June 18, and those travelling to this meeting from the East can take advantage of the summer tourist rates which are even lower than the 25 per cent reduction usually available to members attending Association meetings.

Further information concerning the regional meeting in Portland may be obtained from William C. Hassler, M.D., Department of Health, San Francisco, Calif.

NEW MEMBERS

Mrs. M. W. Ainsworth, Onawa, Ia., Red Cross County Public Health Nurse

Helen G. Andres, B.S., Baltimore, Md., Nutrition Director, Baltimore Dairy Council

 elected 1912.
 Tom Rosenfield, Rock Island, Ill. Member,
 elected 1921.
 Dr. F. H. Lee, Canaan, Conn. Member, elected
 1919.

LETTER TO THE EDITOR

TO THE EDITOR:

Realizing, in the summer of 1925, that Tampa, Fla., should have a modern health department, the City Commissioners endeavored to secure as health officer the best man they could find. Once this became known, they were swamped with applications. Unable to decide among these, they sought the advice of the Board of Trade's Committee on Public Health and Hospitals.

The name of E. C. Levy, M.D., formerly Chief Health Officer and later Director of Public Welfare of Richmond, Va., was not in the list of applicants, but the outstanding character of his work, his national reputation, and the endorsements which their own inquiries brought from high sources led the committee to make a unanimous recommendation in his favor. The City Commission proffered the position to Dr. Levy and he became City Health Officer of Tampa in September, 1925.

He found an utterly demoralized situation. A few employees, without head or organization, constituted the Health Department. Many and peculiar diffi-

culties had to be met. For example, during this period any public statement relating to bad sanitary conditions which needed correction or to the prevalence of contagious disease was resented in certain quarters as harmful to the community. This was shown during the smallpox outbreak which started when Dr. Levy had been here only a little over three months. But here, as always, he stood his ground. He won his fight, both against this opposition and against the epidemic.

When Dr. Levy came to Tampa, the milk supply was about as bad as can be conceived. All previous efforts to improve the situation had failed. Our efforts to secure results through the health authorities had brought about little or no improvement and we had almost lost hope. Frankly, we were at first discouraged at the deliberate manner in which Dr. Levy went at this particular problem, but he called attention to the lack of success which had attended previous lines of action and asked for reasonable time to show results. He outlined his program and

showed how each step had to be established before the next could be taken. As the difficulties were overcome, one by one, those who had doubted were convinced. Tampa has now a thoroughly satisfactory milk supply.

Never discouraged, never yielding to popular clamor either in the direction of courting failure by undue haste or of letting up in a course once decided upon, he succeeded not only in giving Tampa the kind of health department that she had so long needed, but also in winning over those who had been indifferent.

By whatever standard measured, Dr. Levy made good. No single thing perhaps can better substantiate this claim than the practically unanimous endorsement of his work by the medical profession of Tampa. Since his retirement the Hillsborough County Medical Society has elected him an honorary member and is planning to give him a testimonial dinner.

The real purpose of this communication is to make it plain that politics, and politics alone, is responsible for the fact that Dr. Levy is not still in office. Tampa has recently been through a heated and long-drawn-out political campaign. As in many other Florida cities, collapse of the boom brought about conditions which were improperly attributed to the local government. In Tampa this went so far as to cause attacks not only on the City Commissioners but on commission government itself. Finally the people voted in favor of a charter giving Tampa the old system of a city council elected by wards, under the name of "representatives" elected by "districts."

This change in the basic form of government was the only issue considered by the people in voting for the new charter. But in this new charter there is a section relating to the City Health Officer. No training or experience in public health work is required, but he must be a "physician authorized to

engage in the practice of medicine under the laws of the State of Florida." The County Medical Society, through a committee, protested against this provision before the board which was drafting the charter, but this protest was ignored. The people of Tampa had no opportunity to express their views on this particular section. They could only accept or reject the charter as a whole.

Dr. Levy had not, of course, taken the examination of the State Board when he came to Florida to accept the position of City Health Officer of Tampa. At that time Tampa did not have, and no other Florida city at the present time has, any such requirement, nor does the state demand this of its health officer. Even had Dr. Levy been disposed to do so, he had no opportunity to meet this requirement after the adoption of the new charter, since no meeting of the State Board of Medical Examiners was held in the short interval between that time and the time that the charter went into effect.

No reason for not reappointing Dr. Levy was given except that he was ineligible under the new charter.

Tampa has thus, purely through politics, lost a splendid health officer, one who, in the two years and four months that he was in office accomplished great things under most abnormal and trying conditions and who, had he been allowed to continue, would beyond question have given Tampa the same reputation for advanced public health work which, through his efforts, has been enjoyed by his native city of Richmond.

In order not to be misunderstood, I wish to state that I knew Dr. Levy only by reputation before he came to Tampa and since then only through his work here. Such things as have recently happened here and in Chicago should not be.

JOHN H. MILLS, M.D.
907 17th Avenue,
Tampa, Florida.
March 24, 1928.

PUBLIC HEALTH ADMINISTRATION

HENRY F. VAUGHAN, D. P. H.

Smallpox Prevention in New Haven—There have only been 11 cases of smallpox in New Haven during the past twenty years, and none during the past three years until the recent case in January. (There was 1 case reported in January and none in February, 1928.)

As the people of New Haven were exposed to 5 different cases of smallpox during the month of January, only one of which was a resident of the city proper, a determined effort was made to secure the vaccination and revaccination of the city's inhabitants. Of the 5 cases referred to, 2 were in an institution in West Haven, 1 was in the town of Hamden, and the 4th lived about twenty-five miles from New Haven, but was in New Haven up until the onset of the disease.

It is estimated that 100,000 people were vaccinated, 45,000 by the health department, and 55,000 in the industrial plants and by private physicians. There has been no spread of infection. The cost to the city of New Haven including hospitalization will probably be under \$7000.00. The percentage of "takes" in what was considered a well vaccinated community was surprisingly high as shown by figures compiled by the University Health Service, which organization vaccinated 2138 individuals. Of this number 1744 were satisfactorily followed, and of this latter group there were 790, or 47.5 per cent, who gave evidence of a "take"; 808 or 48.7 per cent were immune, indicating protection from smallpox from previous vaccination, and 63 or 3.8 per cent were failures from the first attempt. Those in this last mentioned group were revac-

inated. (The experience of New Haven, which has always been considered a well vaccinated community, and which has religiously practiced vaccination among school children, again indicates that no community can be adequately protected against smallpox unless it practices not only vaccination but revaccination. Had hemorrhagic smallpox secured a foothold in New Haven the result might have been as disastrous as Detroit's experience in 1924. Revaccination is essential.)—John L. Rice, M. D., Prevention of Smallpox Epidemic; *Monthly Bull.*, New Haven Department of Health, LV, 2 (Feb.), 1928.

Tennessee Manual for County Health Departments—Under the direction of Dr. E. L. Bishop, State Health Commissioner of Tennessee, Dr. Joseph W. Mountin has compiled a most interesting manual for the conduct of County Health Departments in the State of Tennessee. The powers and duties of local Boards of Health are defined and particular emphasis is laid upon the relationship between the local units and the state department of health. The administrative features are given in considerable detail. (The reviewer has never seen a more complete document which outlines in a concise and clear manner the organizational features and the control procedures to be followed in a local rural health unit which depends for its existence largely upon a supervisory control system emanating from a state department of health. The manual has appeared in mimeograph form and consists of 165 pages of information which is invaluable to the rural public health administrator.)

Manual for Conduct of County Health Departments, Tennessee State Department of Public Health, Dr. E. L. Bishop, Commissioner.

Diphtheria—"How Complete is Our Protection?"—The *Health Officers' News Letter* issued by the Committee on Administrative Practice for March, 1928, presents some very interesting figures, supplied by the health officers in cities of 10,000 population and over, showing the percentage of preschool and school children immunized against diphtheria. Information was secured from 129 cities, representing a population of over 14,000,000. It was found that approximately 12 per cent of the preschool children in this group are protected against diphtheria and 33 per cent of the grade school group.

The immunization program appears to have been more extensive in Eastern cities over 70,000 among the school age group where the highest percentage of immunity occurs (42.7 per cent), while the lowest percentage (6.4 per cent) is among the preschool children in Western cities from 10,000 to 30,000 population.

From the tabulation carried in this report it is obvious that:

... our diphtheria immunization program has not yet attained such a degree of completeness that we may rest content. The percentage of grade school children still susceptible is sufficiently high to permit the occurrence of a large number of cases, or even a modest epidemic, as did in fact happen in many communities last year. Under existing circumstances the preschool population cannot escape. Health officers would do well to bring these facts before their communities and to encourage a system of reporting successful immunizations so that the local progress of prevention can be charted, without which we proceed blindly in our campaign for greater use of toxin-antitoxin. . . .

Public Health Administration in New Jersey—In 1864, largely through the influence of Dr. Ezra M. Hunt, who was one of the pioneers in the public

health movement in that state (who became the tenth President of the A. P. H. A.), the New Jersey legislature appointed a state commission to report upon the general sanitary conditions of that commonwealth. The Civil War retarded progress in sanitary matters, but a second commission was appointed in 1873 with the same chairman. In 1877 the State Board of Health was created and Dr. Hunt was appointed its secretary. In 1880 a law was passed making compulsory the formation of local boards of health.

The major activities of the state board during the decade ending in 1890 were concerned largely with outbreaks of smallpox, diphtheria and typhoid fever, together with the ever-present malaria which probably included the fevers of obscure origin which were supposedly due to the miasm generated in the marshlands of the Passaic and other river valleys. During the next decade there was a more concerted search for the causes of disease and the isolation of those suffering from specific communicable infection. Isolation hospitals under health board management were advocated. In 1895 a law was enacted requiring physicians to report certain communicable diseases to local health boards. The typhoid fever death rate was reduced from 54 per 100,000 in 1890 to 18 in 1900. There was a great advance in sanitary engineering practice with special emphasis upon the prevention of water-borne typhoid fever.

Soon after the beginning of the new century there were legislative acts providing for medical examination of school children, and creating the State Sewerage Commission. During this decade laboratory service expanded, largely through the influence and energetic work of R. B. Fitz Randolph. The number of local sanitary districts had grown from 200 in 1880 to 434 in 1902.

In 1908 the State Board of Health

was reorganized and combined with the State Sewerage Commission. In 1911 the staff of the State Board of Health consisted of 45 employes, and by 1920 it had increased to 150. In 1915 the State Board of Health was succeeded by the State Department of Health.

Sedgwick played a leading part in the progressive trend of health work in New Jersey through the influence of his students, trained sanitarians, among whom were Parker, Winslow and Wells, at Montclair and Gunn, Osborne, and McNutt in "The Oranges."—D. C. Bowen, *A Half Century of Public Health in New Jersey*, *Pub. Health News*, Dept. of Health, New Jersey, XIII; 35 (Jan.-Feb.), 1928.

Michigan Health Officers' Manual—Rules and regulations for the control of communicable diseases revised and adopted January 1, 1928, have been published by Dr. Guy L. Kiefer, Commissioner, Michigan Department of Health. The bulletin which consists of some 60 pages is divided into four sections, the first of which deals with general considerations involved, including the authority given to the State

Health Commissioner and the State Advisory Council of health in promulgating regulations. There are then propounded certain questions which frequently arise in the mind of the layman with respect to the control of communicable diseases, and these are answered in full.

The second section deals with the scope of the code and specifies the diseases which are declared to be reportable.

The third section consists of definitions of such important control measures as quarantining and isolation, and the general practice to be pursued with respect to carriers, contacts, exclusion from school, and the supervision of contagious diseases on dairy farms.

The fourth section gives the detailed procedure for the administrative control of each communicable disease.

(The code is not unlike that adopted by the American Public Health Association, but is to be especially commended for the clear and concise manner in which the regulations have been enumerated.)—Dr. Guy L. Kiefer, Commissioner, Michigan Department of Health, *Health Officers' Manual*.

LABORATORY

C. C. YOUNG

DISSOCIATION OF THE RAWLINGS STRAINS OF B. TYPHOSUS

NEWTON W. LARKUM, PH.D.

Michigan Department of Health, Lansing, Mich.

THE tendency toward dissociation of bacteria in general and of the organisms of the colon-typhoid group in particular is well recognized; yet very little attention has been paid to the question of the extent of variation or to the significance of many of the varieties encountered. When the bacterium under consideration is other than an animal or human pathogen, the time required for a complete and careful study can well be afforded, but when organisms of such immunological significance as those of the Rawlings strain of *B. typhosus* are concerned, such discoveries as have been made should be applied as quickly as possible. Certainly, uniformity in the cultures of this strain, used in practically all laboratories for the production of the antityphoid vaccine, should be a prime requisite. The prescription of this strain was obviously intended to satisfy such a condition, yet the evidence found in the literature of the past decade is scarcely necessary to indicate to what an extent the facts fail to correspond to the theory. Many who have had occasion to work with two or more subcultures of *B. typhosus* Rawlings have noted certain differences. Such observations have seldom been published, but a study of Robinson's^{2,3} two papers on antigenic differences in strains of *B. typhosus* is sufficient to indicate the wide differences that occur. This knowledge of variations even within a well-studied and much used bacterial strain

only awaited the development of the subject of "Microbic Dissociation" for its explanation and extension.

There is no need in this paper to enter into a discussion of "Microbic Dissociation." Hadley¹ has thoroughly covered the subject. It may be well, however, to indicate briefly some of the major conceptions, first of which is the well established fact that bacteria may and do vary. Within a well established species wide differences in colony appearance, biologic activity, antigenic and physiological characters may exist. However one may feel about accepting the concept of extremes of variation characterized by the S (smooth or normal type) and the R (rough or extreme variant) and the many intermediate forms less definitely described, one cannot help but consider the data which show variations in virulence and antigenic powers associated with certain colony forms. Assuming for the present, that one can definitely separate at least two types, how are they to be recognized? The distinguishing characteristics of the two types, S and R, are mentioned in the following Table I taken from Hadley's review.

Other characteristics might be included, but the above are sufficient for present purposes. While these properties of the two variants serve to identify them, they have other significances which may be readily noticed. Outstanding among these are their virulence

and transformations in immune serum. To come directly to the point about which this paper is solely concerned, the R type, being the less virulent, that therapy or prophylaxis is best which assures a transformation from the (virulent) S to the (non-virulent) R type or at least which will not interfere with what is apparently a *normal* transformation in this direction. In the same sense, that organism which produces an antiserum in which the S (virulent) type is transformed to an R (non-virulent) type and in which there is no tendency for the R types to become S forms, is the one which should be used in the preparation of antityphoid vaccines. In other words, the use of any form other than the S type in vaccines is, on the basis of such evidence as we now possess, unwarranted. With these facts in mind, an investigation of several cultures of *B. typhosus* Rawlings was undertaken not alone to determine what type was actually in use in various laboratories, but to verify certain of the statements made above, particularly those referring to transformations in immune sera. The relative virulence of the two types is apparently well-established, especially in view of the recent contributions of Webster and Burns.⁶

TABLE I

S TYPE

Homogeneous clouding in broth
Normal suspension in 0.8% salt solution
Colonies, smooth, regular, convex
In motile species, active
Carries double antigen (S and O)
If a pathogen—virulent
Sensitive to bacteriophage
Transformed to R in S immune serum
Not transformed in R immune serum

R TYPE

Agglutinative growth in broth
Sedimentary suspension in 0.8% salt solution
Colonies rough, irregular, flat
In motile species, non-motile
Often pure R (may have some O or S)
Slightly or non-virulent
Less sensitive to bacteriophage
Not transformed in S immune serum
Transformed to S in R immune serum

EXPERIMENTAL

Six agar slant cultures of *B. typhosus* Rawlings, subcultures from the strain used in the preparation of vaccines, were received from as many laboratories. Although the various examinations were made as soon as possible after receipt of the cultures, lest the objection be raised that variation occurred during the investigation, transfers were made on agar slants which experience has shown tends to prevent variation for a time at least. Table II

TABLE II

Strain	Colony Type	Growth in broth	Motility	Agglutination in 0.8% salt sol.	Susceptibility to bacteriophage	Agglutination with antisera		Per Cent Transformation ¹ in 10% immune serum broth		Per Cent Transformation in blood broth	Virulence*
						S	R	S serum	R serum		
1	R	Settles	—	Partial	++++ ²	+	—	50%S	50%S	50%S	—
2	R	Turbid	—	None	++++	+	—	20%S	40%S	60%S	0
3	S	Turbid	+	None	++++	+	+	40%R	40%R	100%R	0
4	R	Turbid	+	None	++++	+	+	20%S	70%S	50%S	0
5	R	Turbid	—	Partial	++++	+	—	30%S	30%S	10%S	+
6	R	Turbid	+	None	++++	+	—	30%S	30%S	50%S	+

1. Maximum; based on colony appearance

2. +++++: complete lysis

* Virulence for guinea pigs using two 18-hour slants, intraperitoneal injection

gives the results of these examinations. Two other cultures are included. These have been under observation for several months and are considered representative S and R types, respectively. They were used in the preparation of the R and S. antisera used.

Some further information is necessary before entering into a discussion of the results shown in Table II, especially concerning colony types. No single criterion for the identification of the culture type is so significant as the colony appearance. In many investigations little or no effort is made to go further than to record the colony appearance. That such a procedure is ill-advised can be readily seen from the data presented here. Apparent R types proved on further study to possess many of the characteristics of the S form. Examination of the colonies formed by the above cultures revealed several facts not shown in the table. Each of the strains referred to was apparently homogeneous. There were no variations among the colonies of a single strain when freshly subcultured from an agar slant. On the other hand, the so-called R types were by no means identical. Strain 1 most closely resembled the stock R, while strain 3 was indistinguishable from the known S form. The other four most decidedly favored the R type in appearance. With the exception of 1, all of the strains grew in broth in a manner resembling the S type. Motility tests are misleading because of the fact that here individual bacteria rather than masses of bacteria must be considered. One can usually find some motile organisms in any type of a motile species. However, the difference between the stock S and R was sufficiently marked so that a similar difference determined the question of positive or negative motility with the other strains.

It is not within the province of this paper to consider such theoretical and controversial subjects as the relation of

agglutinability or susceptibility to bacteriophagy, to dissociation. Nor indeed do the few virulence tests performed shed much light on the virulence of the strains tested. If, however, each of the strains is considered with respect to all the data presented, it is possible to reach a conclusion as to its nature. Strain 1 most closely resembles an R type and it is likely that the majority of investigators with experience in this field would classify it as such. Strain 3 would be called an S type. The other four strains cannot be classified as S or R. They have certain attributes of both types, yet one conclusion, at least, can be made. *Five of the six strains studied were not S types.*

There remain to be considered two questions, one of which was raised earlier in the paper: does growth in R immune serum tend to prevent the S→R transformation and to promote the development of S types from R; and how may one obtain the S type for use in the preparation of vaccines. The literature contains but one paper dealing with the first question. Soule⁴ working with *B. subtilis* showed that there is a tendency of R antiserum, not only to preserve the S type as such, but to bring about the R→S transformation. The same writer while recognizing the futility of generalization points out that should these conclusions hold for pathogenic organisms, there is a very real danger from attempting artificial immunization with R type strains. To consider typhoid fever as an example, two situations may be imagined, one in which the individual is invaded with R type organisms, as more frequently happens if carriers are the source of the bacilli; the other where an S type bacillus is concerned. In the first instance, the serum being anti-R, S type organisms result from the invasion. In the second, there is no tendency for the less virulent R type to be formed as happens when anti-S serum is present.

Referring again to Table I, it will be seen that, grown in 10 per cent S serum broth, S type organisms dissociate to R. This fact finds ample confirmation in the literature (Hadley). R types have a tendency to remain as such. It will be seen that even here there is some reversion of R→S, but comparison with growth in normal and R immune serum broth shows it to be relatively slight. In R and in normal serum broth, the S type remains S while the R has a very marked tendency to become S.

S types for immunization purposes may be produced by growth of the strain in question in R anti-serum. Frequently, however, such serums are not available, and some strains are less affected than others by such treatment. That animal passage gives a satisfactory solution to the problem is indicated by the following experiment. Cultures from several R type colonies were injected intraperitoneally into guinea pigs using the washings from two agar slants. Twenty-four hours later, heart's blood cultures were taken from dead as well as surviving animals and in none of 26 cultures was an organism other than *B. typhosus* obtained. All of the organisms were of the S type with the exception of those obtained from the animals receiving the stock R culture. Todd⁵ observed that extreme R type cultures of hemolytic streptococci would not revert to S types on animal passage. The result of

the above experiment would indicate that the same is true for typhoid strains. Except when extreme dissociation has occurred organisms may be converted into S types. Thus, it is recommended that frequent animal passages should be made of cultures of *B. typhosus* Rawlings if they are to be used in the preparation of anti-typhoid vaccines.

CONCLUSIONS

Five of 6 strains of *B. typhosus* examined with respect to their degree of dissociation were found to be other than S type.

The report of Soule that growth of R types in S immune serum results in the production of S types, and that the tendency of S types to dissociate to R is inhibited by such serum was confirmed for the typhoid bacillus.

Passage of forms other than the extreme R type through guinea pigs results in a reversion to pure S types.

VITAL STATISTICS

LOUIS I. DUBLIN, PH.D.

Infant and Maternal Mortality in the United States—In the period for 1915 to 1924 there was a decrease of 29 per cent in the total infant mortality rate in the registration area. The decreases in the rates for the urban and rural areas were very similar—30 per cent for the urban and 27 per cent for the rural. The improvements in the rate for white infants in the total registration area, in the urban area, and in the rural area are strikingly similar—32 per cent, 32 per cent, and 31 per cent respectively. The mortality rate among colored babies in the country has decreased 42 per cent in the decade under consideration. This is interesting in view of the fact that undoubtedly no class of the infant population has been less affected by so-called infant welfare work.

Unfortunately the United States cannot show a downward trend in maternal mortality. There was a rise of 8 per cent in maternal mortality from all puerperal causes in the total registration area from 1915 to 1924. In urban areas there has been a rise of 14 per cent—from 6.4 to 7.3 per 1,000 live births. The rural areas show an increase of 5 per cent. The only decrease shown in the maternal mortality from all puerperal causes is in the rate for white mothers in rural sections, which has fallen from 5.5 to 5.1—a decrease of 7 per cent. In the total registration area the rise in the rate for whites is very slight—less than 2 per cent—but in urban areas alone the rise has been 11 per cent. The rates for colored mothers show increases in the total registration area, in the urban, and in the rural area, of 11 per cent, 17 per cent, and 34 per cent, respectively. Deaths from puerperal septicemia com-

prised over 36 per cent of the total maternal mortality. Though there is a slight increase from this cause in the total urban rate and in the rates of white city women and colored country women, in every other instance the rates show a tendency either to fall or to remain more or less stationary. In other accidents of labor (puerperal hemorrhage having been eliminated) and albuminuria and convulsions—there seems to be a slight rising tendency. The rate for the former has risen 13.3 per cent and for the latter more than 7.5 per cent.—E. Blanche Sterling. *Pub. Health Rep.* 43:497-503 (Mar. 2), 1928.

Demographic Statistics for Germany—The average length of life, in 1900-1911, in the German empire was 49 years. The total number of deaths dropped from 1,261,000 (30.6 per 1,000) in 1872, with some fluctuations of the total, to 1,206,000 (22.5 per 1,000) in 1897, and to 1,154,000 (18.1 per 1,000) in 1909, the year in which, for the last time, more than 2 million births were recorded. In the last normal year, before the World War (1913), the number of deaths had dropped to 1,061,000 (15.8 per 1,000). In 1923, 1924 and 1925 the total number of deaths was, respectively, 901,000 (14.6 per 1,000), 802,000 (12.9 per 1,000), and 788,000 (12.6 per 1,000).

The birth rate increased up to 1901, since which year there has been a decline. From 1872 to 1874 the total number of births ranged from 1,700,000 to 1,750,000, and from 1875 to 1890 the range was between 1,750,000 and 1,840,000. Between 1891 and 1897 it rose, with slight fluctuations, to 1,991,000.

The decade from 1898 to 1909 showed the greatest annual totals of births; they run over 2 million. Since 1909 the figures have again slowly declined to 1,874,000 in 1914. The years 1923, 1924 and 1925 showed a more uniform picture, the total births in those years having been, respectively, 1,340,000, 1,314,000 and 1,335,000. Comparative figures reveal a slow decline in the birth rate from 40 plus per 1,000 population up to 1879, to 38 per 1,000 in 1888 (38 was reached again in 1891 and 1893). In 1899 the rate fell to 37 and in 1902 to 36.2 per 1,000. In 1906 a rate of 34 per 1,000 was attained for the last time; in 1908 the rate dropped to 33. Then the rate dropped abruptly to 27.6 during the second, the last normal, quarter in 1914. From 1923 to 1925 the figures are fairly uniform: 21.7, 21.1 and 21.3, respectively. The larger cities in spite of a high percentage of marriages, had only 14.2 living births per 1,000 of population; Berlin had a birth rate of only 9.5. The rural sections are rapidly coming to follow the example of the larger cities and the upper classes. In 1898 the excess of births over deaths for the German empire was 15.6 per 1,000 population (the highest figure); the average figure for the period 1871-1880 was 11.9; for 1881-1890, 11.7; for 1891-1900, 13.9, and for 1901-1910, 14.3. For 1913 the last normal year before the war, the excess of births over deaths was only 12.4 per 1,000. The excess of births over deaths in 1920 was 10.8, and in 1921 it rose even to 11.3. But even this peak of the postwar figures was under the figure for 1913. During the period from 1922 to 1925 the figures were fairly uniform, ranging around 8.1 per 1,000, as follows: 8.5, 7.1 (height of the economic depression due to the decline of the mark), 8.2 and 8.7, respectively. The birth rate and the death rate are both declining, but the birth rate is declining more rapidly than the death rate. —*J. A. M. A.*, 90:787 (Mar. 10), 1928.

Maternal Mortality in Canada—The special inquiry into maternal mortality in Canada has been completed after several years of study and the report was issued at the beginning of this year. There were 237,199 living births from July, 1925, to July, 1926, and 1,532 of the mothers died from maternal causes, giving a mortality rate of 6.4 per 1,000 living births. The ages of these mothers varied between 15 and 48 years with an average age of 31.1 years. Three hundred and forty-nine were primiparae and 963 were multiparae. These latter 963 mothers left 4,305 motherless children, an average of 4.5 children per mother.

In 385 cases (25 per cent of total) the birth occurred in a hospital; 48, or 3 per cent, were attended by midwives. In 128 cases, or 8 per cent, of the total the doctor was not called until the patient was in labor. In 27 cases the doctor was not called until the patient was dying and in 91 the doctor was not called until several days after the birth, while in 101 there was no doctor present at any time during the birth or after it. Only 230, or 15 per cent, of the mothers had any prenatal care and in 40 of these the instructions were not followed. In 110 cases, death occurred before labor began.

Puerperal septicemia was given as the cause of death in 418, or 27 per cent, of the cases but this percentage would probably be raised if the histories had been more fully given in some cases. Hemorrhage was given as the cause of death in 357, or 23 per cent, of the total, heart disease in 226 cases, and eclampsia in 195 cases. Influenza and pneumonia, singly or together, had an influence on the mortality in 132 cases, tuberculosis in 96, embolus and dystocia in 87 each, nephritis in 80, placenta praevia in 76, shock in 63, anemia in 44, ectopic pregnancy in 33, phlebitis in 22 and venereal disease in only 9 cases. Previous pregnancies, too frequently and at too short

intervals, were mentioned in 19 cases, 67 patients were called overworked with the care of their other children and the home and 27 said to have had insufficient sleep and rest. The general health of the patient was given as poor or bad in 153 cases, 30 had serious infections of the teeth, and 10 infected tonsils.

Forceps were used in 289 cases, or 19 per cent of the total, and 136 operations were performed. Pituitrin was used in 327 cases, or 21 per cent of the total and rupture of the uterus was reported in 3 of these cases. In 5 cases it was used before labor, in the first stage in 9 instances, in the second stage 123 times, and in the third stage, in 32 cases and postpartum in 50 cases. During or after caesarian section it was used in 11 cases.—Department of Health, Canada. *Pub. No. 37. The Little Blue Books National Series No. 1, 1928.*

Vital Statistics in Connecticut, 1927—Connecticut in 1927 had the lowest death rate in the 78 years for which the vital statistics of the state are available, according to a provisional summary issued by the State Department of Health. The death rate last year was 10.5 for each 1,000 population, or 16,661 deaths in an estimated population of 1,586,435. During the same year 28,473 births were reported. In 1925 the death rate was 11.6; in 1924 it was 11.3 and in 1923 it was 12. Last year's records also show the lowest infant mortality in the history of Connecticut, 60 per 1,000 live births.

The death rate from typhoid fever during 1927 reached a new minimum of 1.1 for each 100,000 population, there being 17 deaths in 1927 against 29 deaths, a rate of 1.8, from this disease in 1926. The typhoid death rate has been falling steadily from a maximum of 41.8 in 1890. The 1927 death rate for measles showed a sharp drop, from 195 deaths, a rate of 12.5 for each 100,000 population, in 1926, to 21 deaths, a rate

of 1.3 in 1927. The scarlet fever death rate shows a steady decrease, from 53 deaths, a rate of 3.6 in 1923 to 22 deaths, a rate of 1.4 in 1927. Whooping cough during 1927 had the lowest death rate in the history of the state, there being 40 deaths, a rate of 2.5 and in 1926, 95 deaths, a rate of 6.1. The death rate from diphtheria showed an increase in 1927 over that of 1926. The total deaths in 1927 were 94, a rate of 5.9; compared with 83 deaths, a rate of 5.3 in 1926. The 1927 diphtheria death rate is next to the lowest in the history of the state, the 1926 rate being the lowest on record, the lowest rate until that time having been 8.2 in 1921. The highest diphtheria rate recorded was 97.7 per 100,000 in 1889. In 1923 there were 187 diphtheria deaths, a rate of 12.7; in 1924, 168 deaths, a rate of 11.2 and in 1925, 126 deaths, a rate of 8.2.

The death rate from influenza in 1927 was 18.8, but little more than half the 1926 rate of 35.9. There has been a downward trend in the tuberculosis death rate since 1918, but the number of cases for the last five years has been practically stationary. Last year there were 925 deaths from pulmonary tuberculosis, a rate of 58.3 and 134 deaths from other forms of tuberculosis, a rate of 8.4. There was a distinct upward trend in the cancer death rate to 1925, but since that year, because of some unknown factor, the death rate has been practically stationary. There were 1,646 cancer deaths a rate of 107.6 in 1925; 1,663 deaths, a rate of 106.7 in 1926 and 1,683 deaths, a rate of 106.1 in 1927. The pneumonia death rate in 1927 was very low, 84.4, the first time in recent years, according to Commissioner Osborn, that the rate has been below 100. In 1926 there were 1,693 deaths, a rate of 108.6. In 1927 there were 1,339 deaths.

Poliomyelitis showed an increase from 6 to 16 deaths from 1926 to 1927, due to the outbreak last year, and the death

rate showed a corresponding increase from 0.4 to 1.0. Cerebrospinal meningitis had a death rate of 0.6 for both 1926 and 1927, there being 10 deaths from this disease in each year. The lower infantile mortality rate in 1927 was in a considerable measure due to the drop in the death rate of children under 2 years old of diarrhea and enteritis from 16 in 1926 to 11.1 in 1927. There were 188 suicides in the state in 1927, a rate of 11.9 per 100,000, while during the preceding year there were 216 deaths, a rate of 13.9, which was the highest for the 5-year period. Deaths from accident in 1927 numbered 1,051, a rate of 66.2, the lowest for the 5-year period. The highest accident death rate during the 5 years 72.6, representing 1,111 deaths, was in 1925.—*Hartford Courant*, Feb. 4, 1928.

Correlations Between the Death Rate from Diabetes Mellitus and Certain Demographic Factors—An inquiry into the relationship between the diabetes death rate and some demographic factors in various localities showed the following numerically significant correlations:

There was a high negative correlation with the percentage of negroes in the population. In 66 large cities this was -0.538 with the coefficient 9.1 times its probable error; in 34 states it was -0.731 and the coefficient 13.5 times its probable error. There was a positive partial correlation in the large cities with the percentages of the total population born in Ireland ($+0.561$), Germany ($+0.325$), Italy ($+0.380$), and Russia ($+0.441$). The zero order correlation with the percentage of Polish population was insignificant, but correction for age gave a first order coefficient of $+0.410$ which was 5.9 times its probable error.

The zero order correlation between the diabetes mortality (corrected for age and sex) and the proportion of the

population filing income tax returns was $+0.727$ which is 13.2 times its probable error. The correlation with the cancer death rate was $+0.842$, which was 38.3 times its probable error. Tuberculosis of the lungs had a significant negative correlation and organic heart disease a significant positive correlation, acute nephritis and Bright's disease and pneumonia have insignificant correlations, the former correlation being negative and the latter positive. The correlation with incidence of defective and deficient teeth among drafted men was $+0.314$ almost 3.0 times its probable error, correction for percentage of population residing in urban areas reduces this to $+0.052$ which is 0.4 times its probable error. The correlation of the age- and sex-adjusted death rate from organic heart disease with the incidence of defective and deficient teeth gave a coefficient 5.5 times its probable error. Both diabetes and cancer mortality show significant positive correlations with the incidence of obesity among drafted men, the diabetes coefficient being 4.6 times its probable error and that of cancer 6.2 times the probable error.—Robert Jordan, *Am. J. Hyg.* 8:55-67 (Jan.), 1928.

The Age Distribution of Poliomyelitis—Approximately 50 per cent of all cases of poliomyelitis occur under 5 years of age, 80 per cent under 10 years, 90 per cent under 15 and 95 per cent under 20 years in urban communities, but in rural areas it is more evenly distributed through the older age groups. A comparison with measles and diphtheria showed the age distribution of the three diseases to be of the same order and the incidence in the various age groups to be directly proportional to concentration of the population.

There is strong inferential evidence that the majority of individuals become immune to the virus of poliomyelitis and that this immunization takes place relatively earlier in life with increased

density of population, supporting the theory that the virus is spread by contact to a great extent through abortive cases and healthy carriers. The frequency with which the different viruses cause disease or subclinical immunity has been formulated as follows: of susceptible individuals exposed to measles 1 out of 1 develops the disease; of those exposed to diphtheria 1 out of 10 develops the disease and 9 out of 10, subclinical immunity; of 100 susceptible individuals exposed to poliomyelitis 1 develops the disease and 99 subclinical immunity. Consequently there are no healthy measles carriers, in diphtheria there are about 9 potential healthy carriers to every case, and in poliomyelitis about 99 carriers to each recognized case.—W. Lloyd Aycock—The Significance of the Age Distribution of Poliomyelitis. Evidence of Transmission through Contact.—*Am. J. Hyg.* 8:35-54 (Jan.), 1928.

A Study of the Use of Convalescent Measles Serum in Children's Institutions—There were 945 cases and 51 deaths from measles in 40 children's institutions in New York State in 1923. Seventy-seven per cent of the deaths were in children under 3 years of age, about the same proportion as in the state at large. There were no deaths among the 6 cases in children less than 6 months of age. The highest fatality rate was in children between 6 and 11 months of age, after this age it declined rapidly. There were only 3 deaths among the 560 cases in children aged 5-19 years, this fatality rate of 0.53 per cent, however, was 3 times as high as that for the same ages in the state as a whole. The fatality rate at all ages in 1923 was 7 times as high for the institutions as for the state.

In its prophylactic properties the use of the serum was decidedly disappointing. Among institution children at least the serum seems reliable only where

given within 6 days to children who have been exposed to small doses of infection for only a short time. If given during the incubation period it will probably have a favorable influence on the mortality, but under exceptionally adverse conditions it is inadequate. In 1923 the fatality rate for children under 3 was almost twice as high for untreated children as for those given serum (74 cases with 9 deaths as against 65 cases with 4 deaths). On the whole, however, the figures for the combined years 1923 and 1924 for children under 3 are slightly in favor of the cases not treated with serum. This is probably partly due to the small number of cases under consideration and to the decidedly unfavorable circumstances in which, in 2 of the outbreaks, the serum was used.—Edward S. Godfrey, Jr. *J. Prev. Med.* 2:11-33 (Jan.), 1928.

Vital Statistics in Iowa, 1927—Provisional figures for 1927 show a slight but encouraging decrease in the death rate in Iowa. The total number of deaths was 24,237 as compared with 25,466 the year before, and 24,619 as the average for the 5-year period from 1923 to 1927 inclusive. Heart disease again heads the list of causes of death; 4,846 persons died of heart disease in 1927 as compared with 3,970 for 1926 and 3,299 as the average for the 5-year period. Cancer caused 2,646 deaths in 1927 and 2,593 in 1926.

Cerebral hemorrhage, third highest cause of death; pneumonia, fourth; nephritis, fifth; tuberculosis, sixth, and influenza, seventh, all show a commendable decrease as compared with 1926. There were only two diseases in which there was a significant increase in the death rate. These were measles, which caused 210 deaths, and poliomyelitis (infantile paralysis) which caused the death of 29.—Iowa State Dept. of Health. *Weekly Health Message*, Feb. 25, 1928, p. 2.

PUBLIC HEALTH ENGINEERING

ARTHUR P. MILLER, C.E.

GREAT LAKES DRAINAGE BASIN AGREEMENT

LEWIS S. FINCH

*Director, Water & Sewage Department,
Indiana State Board of Health, Indianapolis, Ind.*

AN agreement providing for interstate cooperation in handling stream pollution problems, occurring within the Great Lakes Drainage Basin, was drafted March 7, 1928, at Gary, Ind., by the State Health Commissioners, or their representatives, of Minnesota, Wisconsin, Illinois, Indiana, Michigan, and Ohio. The State Health Departments of Pennsylvania and New York were not represented at this meeting, but their executive officers had previously expressed their willingness to become parties to such an agreement.

This agreement, which is to be officially known as the "Great Lakes Drainage Basin Sanitation Agreement," follows the general lines of the interstate agreement of the Ohio River Drainage Basin which has now been in effect for four years.

The purpose of the Great Lakes compact is defined in the following resolution:

WHEREAS the Great Lakes (Superior, Michigan, Huron, St. Clair, Erie and Ontario) are used as the only available sources of public water supplies by many municipalities in Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, Pennsylvania and New York, and such use must of necessity increase with the future increase of population; and

WHEREAS the protection and promotion of the public health demand that the water of these lakes and their tributary streams shall be suitable to permit the production of safe, wholesome, and palatable water supplies, after reasonable purification; and

WHEREAS sewage and industrial wastes are now discharged to the said lakes and many of their tributaries to an extent affecting the safety, wholesomeness, or palatability of water supplies obtained therefrom; and future increase in the pollution of these lakes and their tributaries will occur unless suitable corrective and preventive measures are applied; and

WHEREAS the said lakes and many of their tributary streams are interstate lakes and streams common to the States of Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, Pennsylvania, and New York, and pollution thereof originating in one state does or may prejudicially affect public water supplies, public health, or public interest in a neighboring state or states, thus creating a problem of common interest, and requiring cooperation between the several states; therefore be it

RESOLVED that the Departments of Health of the States of Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, Pennsylvania and New York, represented by the executive officers of the said Departments of Health, do hereby agree to cooperate with each other and with the United States Public Health Service in carrying out a policy for the improvement of the quality of the waters of these interstate lakes and their tributary streams wherever necessary in these states, the prevention or correction of undue pollution thereof, to the end that the said lakes and tributary streams may be maintained or rendered suitable sources of public water supplies as aforesaid.

At the Gary meeting, Dr. Wm. F. King, State Health Commissioner of Indiana, was elected chairman and Dr. I. D. Rawlings, Director of the Illinois Department of Public Health, secretary.

The resolution, as drafted at Gary, has now been submitted to the executive boards of the various state health departments for ratification.

After this action has been taken by these boards, it is expected that the state health commissioners will again meet, and among other things, authorize the formation of a board of engineers, composed of the chief engineers of the several departments of health.

This board will be charged with carrying out the spirit of the agreement which essentially is that each state health department, agrees to exercise "conscience" in dealing with the matter of stream pollution as affecting other states.

Malaria in Haiti—This brief article is a very clear picture of the high points of malaria in Haiti, and a good description of the island in relation to mosquito production. Haiti has only one efficient vector of malaria, *A. albimanus*. This anophelese is capable of transmitting all three types of malaria. The authors give their reasons for believing that malaria was imported into Haiti and is not of native origin.

The island is small, having but 10,200 square miles; less in area than the State of Maryland, yet it has all kinds of climate—from tropical on the coast to temperate in the hills. The most important plateau is a large central plain approximately 1200 square miles in area. Parts of the island are desert-like in their dryness; other portions are exceptionally wet. Late summer and winter are the malarial seasons. *Albimanus* breeds all over the island wherever water collects and has been found up to 2500 feet above sea level. Rainfall varies in different parts of the island from a minimum average of 21.7 inches annually (portion of the island where the runoff dries quickly, non-malarious) to 167 inches in the most malarial part.

Malaria is very prevalent and severe.

Splenic index in a large number of school children shows rates varying from a minimum of around 2 per cent to a maximum of 100 per cent. Many schools show rates between 20 per cent and 60 per cent.

The problem of control differs in type in the rural and urban centers. It is the authors' belief that rural districts must at present depend solely upon adequate quinine treatment of those sick. Many of the cities practice mosquito control, and it is advised that the rest of them initiate its practice.

A. albimanus quickly begins breeding in new swampy places formed by heavy rains, thus differing from our *quadrimaculatus*. The malaria infection very closely follows the rainfall, lagging behind about two months.

Control work at Port au Prince is described in a general outline. It was an extensive piece of work. *Albimanus* was breeding in many of the street ditches, in seepage areas, and the nearby extensive swamps. For the ditch breeding and the seepage, the attack was drainage and fill. Rock drains (earth covered) were used extensively with success. Much of the swamp land was dried by complete clearing of brush and opening it up to process of evaporation. Some of the swamps were drained, and low portions were filled. Apparently the major portion of the work has now been completed, but there is yet some which remains to be done. The tables giving malaria infection by months for a number of years show a steady decline in the case rates from a January rate (1924) of 1350 per 1,000 to the January rate (1926) of only 125 per 1,000—C. S. Butler and E. Peterson. *U. S. Nav. Med. Bull.*, 25:278 (Apr.), 1927. Abstr. L. L. Williams, Jr.

An Experiment in Mosquito-Proofing Barracks of British Troops—The article covers experimental screening of certain barracks at Lahore

and Amritsar, plains stations in the Lahore Military District, India. These two stations are located in the flat country having poor drainage, and are the most malarious of all Indian stations.

Anti-larval work has been carried on for many years as has personal protection by the use of mosquito nets, mosquito lotions, fumigations, etc. Not all of the barracks at these two stations were screened. Barracks screened were long, single story, bungalow type, having a 12' wide verandah on one side. These verandahs were pierced by a series of archways, the only openings to the verandah. A stout wooden framework was made in each archway and covered with brass wire gauze, 16 mesh, over which one-half inch rabbit netting was nailed for protection. Doorways were double screened with a 10 foot screen gangway between the doors. Doors opened outward and were fitted with double springs. Windows were screened on the outside. Fire places were temporarily filled with brick during the warm weather and all ventilators covered with wire gauze. One man per barrack room was detailed for the sole duty of keeping screens in good repair. It was made a court martial offense to prop a screen door open or to pass a door so propped without removing the obstacle.

In addition to malaria prevention, other advantages were the dispensing with mosquito nets which allowed the lowering of punkhas, the absence of flies and non-biting insects as well as pest mosquitoes and the actual lowering of the temperature in the rooms.

Malaria was as prevalent in the unscreened buildings at these two barracks in 1926 as in any other preceding year. During 1926 the malaria rate in the screened barracks in Amritsar was one-fourth the average rate for the three preceding years and at Lahore one-fifth. At Lahore the rate was less than one-third in the unscreened barracks.

The writer concludes that the screen-

ing of barracks properly carried out is a means of reducing malaria among troops, but cannot be considered as a sole antimalaria measure, its efficacy being more or less in inverse ratio to the evening attractions outside the barracks.—A. Campbell Munro. *J. Roy. Army Med. Corps*, 49:248 (Oct.), 1927. Abstr. R. E. Tarbett.

The Aluminate-Alum Coagulation of Water—Alum has been used almost universally as a coagulant in water purification, but its use with certain waters, or under certain conditions has not been satisfactory. In some waters in the Great Lakes region, 0.2 to 0.4 gr. per gallon is an efficient dose, but some plants in other sections require as much as 5 or 6 gr. per gallon. Studies of these phenomena have shown that colloidal waters do not yield readily to treatment by alum. The application of hydrogen ion control resulted in great advances, but the principles of colloid chemistry, it is felt, will yield still further advances.

Many workers have sought a coagulant that would meet the conditions required by their water supply, and also yield an effluent of sufficient alkalinity to be non-corrosive. Sodium aluminate therefore came into use, but was not entirely satisfactory, until a certain type of the chemical, possessing in itself colloidal properties, was used. Further research is now going on. An account of the results at several plants is given.—C. H. Christman. *Bulletin 18-A*, issued by Chicago Chem. Co. Abstr. W. A. Hardenbergh.

Disposal of Drainage from Coal Mines—Coal mine drainage waters contain sulphuric acid in such quantities that the alkalinity of 80 to 100 gallons of fresh water is necessary to neutralize the acidity of 1 gallon of waste. Coal is produced in 28 states at a rate of 550,000,000 tons annually, and the

industry employs 850,000 men. The pollution is most acute in West Virginia, Pennsylvania and Ohio. Many water supplies in Pennsylvania have been abandoned due to mine drainage pollution. The Sanderson case dating back to 1886 is summarized. In this case the courts held that trifling inconvenience to individual riparian owners must give way to a leading industrial interest of the state.

The Indian Creek pollution suit is also summarized. In this case, a water company serving 75,000 people and the Pennsylvania Railroad obtained an injunction, which was sustained by the U. S. Supreme Court, prohibiting the discharge of mine drainage into Indian Creek above the diversion of its waters, on the ground of public nuisance being created. In this case a public use of the water was shown and no other supply was available.

The character and composition of various mine drainage waters are given and analyses are shown in tables. The occurrence of water in mines is described. Methods of treatment and costs are given. The cost to neutralize (but not redeem) streams in Pennsylvania alone is estimated at \$75,000,000 for plants and \$41,062,500 to \$68,437,500 annually for operation.

The author suggests that any solution must be economically sound and commends the policy of the Pennsylvania Department of Health which is to protect all unpolluted streams; to stop further pollution of all streams that can be restored; and to use those now destroyed for carrying sewage, industrial wastes and mine drainage.—Andrew B. Crichton. *Water Works*, 66:30 (Jan.), 1927. Abstr. E. A. Reinke.

The Treatment of Sewage by Activated Sludge—The author, after a survey of the literature, concludes that the activated sludge process is of bacterial origin. The quantity of activated

sludge must be proportioned to the consumption of the organic matter of the liquid, to the nature of these, to aeration, to the condition of the sludge, and to temperature.

It is necessary to aerate sufficiently to maintain the best bacterial flora, and to proportion the aeration to the activity of the bacteria, to the quantity of organic material to be acted upon and to the quantity of sludge in order not to pass the moment when the sludge itself is altered and commences to putrefy. The sludge should be settled well and should retain but little of the suspended solids.—*Annales d'Hygiene Publique, Industrielle et Sociale*, T. IV, n° 12, Decembre 1926. p. 732. Abstr. R. C. Beckett.

Use of Hypochlorites as a Sterilizing Agent for Dairy Utensils—Since disinfectants containing hypochlorites have been used for the sterilization of dairy utensils, and it has been claimed that such disinfectants are more effective than steam sterilization, this question was studied in the interests of the milk industry. Three proprietary disinfectants were studied. These contained "available chlorine" as follows: A—1.22 per cent; B—1.06 per cent; C—0.45 per cent.

Four series of experiments were conducted upon milk churns of 10 and 17 gallons capacity and the influence of different methods of treatment of the churns upon the keeping qualities of milk and upon the bacteriological condition of the churns studied. The technic used in performing the experiments is given and the results are tabulated in the form of protocols.

The authors give their conclusions as follows: (1) The amount of "available chlorine" contained in these disinfectants varied from 1.23 per cent in disinfectant A to 0.49 per cent in disinfectant C; (2) a 6 per cent solution of disinfectant A failed to give the same

degree of sterility in a churn as can be obtained by steam under working conditions; (3) the use of a chlorine preparation as a means of sterilizing churns necessitates the subsequent washing out of the churns with water if the chlorine is to be removed before milk is added. This process introduces the danger of recontamination of the churn; (4) if the churn be not washed out after treatment with a chlorine preparation, there is grave danger that chlorine will be added to the milk. That this danger is not altogether hypothetical would appear to be the case since in the United States where this method of sterilization is more extensively used than in this country, the Department of Agriculture has issued a bulletin describing a method for the detection of hypochlorites and chloramines in milk and cream. (U. S. Department of Agriculture *Bulletin No. 1114*, Aug., 1922).—W. A. Hoy and Janet R. L. Rennie. *J. Hyg.* 26:127 (July), 1927. Abstr. P. R. Carter.

Sewage Farm Covers 13,602 Acres
—An abstract of an article in *The Engineer* (London) November 12, 1926, p. 519, describes the method of sewage disposal of Melbourne metropolitan area (Victoria, Australia). The land was "originally treeless, almost stoneless, open plain country somewhat clayey and poorly grassed," having an average annual rainfall of 18.14 inches.

The farm is sown with lucerne, pasture grasses and clover and flooded with sewage and used for raising hay and for grazing. Except in winter or very wet weather, the farm takes 3 inches of sewage every 2 or 3 weeks or 5½ feet per year; 8,084 acres being

under irrigation. Dairying is not permitted, but grazing and raising cattle and sheep are carried on. On June 30, 1925, there were 6,671 cattle, 4,947 sheep, and 800 horses with 200 employees on the farm. Revenue from grazing usually is greater than cost of sewage treatment aside from capital charges, while in years of drought revenue meets all charges.—*Eng. News-Rec.*, 99:669 (Oct. 27), 1927. Abstr. A. S. Bedell.

Preliminary Report on a Rat and Flea Survey of the City of San Juan, Porto Rico—While rat extermination has been practiced at San Juan following two epidemics of plague, no real study of fleas infesting the rats was made until recently when such a project was undertaken in coöperation with the U. S. Public Health Service.

The town was divided into four zones: (1) docks; (2) water front adjacent to docks; (3) commercial districts not on water front; (4) remaining portions. Traps were set daily in each zone and all live rats were taken to the laboratory for examination. Classification and counts of rats and the infesting fleas were made.

Concentration of the species of rats was higher along the water front and from data already collected it appears that the species "*mus rattus*" was the favorite host for fleas. The per cent of rats infested with fleas when plotted graphically follows very closely the corresponding curves for temperature and relative humidity, suggesting a relationship.—Arturo L. Carrion. *Porto Rico Rev. Pub. Health and Trop. Med.* 3:131 (Oct.), 1927. Abstr. D. W. Evans.

INDUSTRIAL HYGIENE

EMERY R. HAYHURST, M.D., AND LEONARD GREENBURG, PH. D.

Budapest Congress Progress Report—The Fifth International Medical Congress for Industrial Accidents and Occupational Diseases is definitely announced to be held in Budapest, Hungary, September 2-8, 1928. National committees have been formed in the principal countries.

Since the first American announcement of December 1, 1927, Dr. Fred H. Albee, New York, and Dr. Emery R. Hayhurst, Ohio State University, Columbus, both members of the Permanent International Committee, have been appointed Joint Chairmen of the National Committee for the United States, and have appointed Dr. Richard Kovacs, New York, as Secretary.

The Travel Study Club of American Physicians, of which Dr. Fred H. Albee is President and Dr. Richard Kovacs, Secretary, has rearranged its summer trip for 1928 especially to focus upon the Budapest Congress. Those who have already indicated their intention of attending the Congress and others are invited to join the Travel Study Club either for the entire trip or at any point.

The itinerary thus far arranged calls for sailing from New York on the S.S. Munchen, of the North German Lloyd, on August 16; three days in Berlin, two days in Carlsbad, five days in Budapest, two days in Vienna, two days in Bad Reichenhall and Salzburg, and two days in Munich; then via Milan to Nice for two days and from September 17 to 27 in Spain; sailing from Gibraltar on September 28 on the S.S. Conte Grande, of the Italian Mediterranean Service, due back in New York on October 5.

Correspondence regarding the trip should be had with Dr. Richard Kovacs, 223 E. 68th St., New York, N. Y.

National Delegates to Budapest Congress—Certificates of delegation have been issued over the signature of Frank B. Kellogg, U. S. Department of State, to represent the United States at the Fifth International Medical Congress of Industrial Accidents and Occupational Diseases, to be held at Budapest, Hungary, to the following persons: Dr. Fred H. Albee, New York, N. Y.; Dr. Francis Dennis Donoghue, Boston, Mass.; Dr. Emery R. Hayhurst, Columbus, O.; Dr. Francis D. Patterson, Philadelphia, Pa.; Passed Assist. Surgeon O. M. Spencer, U. S. Public Health Service.

Fourth International Conference of the Permanent Committee on Occupational Diseases—According to a circular received February 15, 1928, this Conference is to be held at Lyon, France, April 3-6, 1929. The Organization Committee consists of: Dr. Agasse-La Font, Dr. Kohn-Abrest (Paris), and Professeur Etienne Martin (Lyon). The officers of the Conference are: President, Professeur Etienne Martin; Secrétaire, Dr. Mazel; and Trésorerie, Imprimerie A. Rey.

The particular items for discussion will be: silicosis, including etiology, symptoms, and legislation (Professor E. L. Collis of Cardiff, will be one of the respondents); pneumoconiosis, author yet unnamed; cataract of occupational origin, particularly with reference to etiology and symptoms (Professor Rollet of Lyon will be one

of the respondents); and the endocrine system in relation to intoxications (Professor L. Ferrannini of Cagliari will be one of the respondents). Names of others who would like to read papers upon the above listed subjects should be sent either to the Secretary Dr. Mazel 54, Avenue de Noailles, Lyon, or to one of the members of the Permanent Committee in the United States, viz., Dr. Alice Hamilton, School of Public Health, Harvard University, Boston, Mass., Dr. Cecil K. Drinker, same address, or Dr. Emery R. Hayhurst, College of Medicine, Ohio State University, Columbus, O.

Circulars of information are to appear from time to time and all interested will get in touch with either Dr. Mazel or one of the members of the American Committee.

Infective Jaundice Among Scotch Coal Miners—The British Medical Research Council recently reported 17 cases with 5 deaths of infective jaundice among Scotch miners since 1923, and in all Scotland they report 31 cases with 8 deaths, giving a mortality of 25 per cent.

These cases occurred in mines that were wet and infested with rats. Similar cases have occurred in all parts of the world and especially during the late war among soldiers in the trenches. The spirochetel origin was demonstrated in Japan in 1915. In 1916, an anti-spirochetel serum was developed which was and is quite effective in treating this disease.

Examination of rats in the infested areas showed 36 per cent infected. At autopsy, 6 cases presented an intense yellow color, effusive hemorrhages, and kidney degeneration. The liver showed degeneration to a lesser degree.

Experimental infection of guinea pigs leads to the belief that infection occurred through the skin and contaminated hands rather than through ingestion.

Eliminative measures suggested are immunization, lime nitrogen on the soil, extermination of rats and drainage of mines. — *Mon. Labor Rev.*, 26:54 (Mar.) 1928.

Asthma Caused by Castor Beans—This report, by Karl D. Figley, M. D., and Robert H. Elrod, M.D., is in January 14 issue of the *Journal of the American Medical Association*. The existence of an "asthma colony" in a certain section of the city of Toledo, O., has been known to physicians for some years. A mill in the vicinity manufacturing both linseed and castor oil, while suspected, had not previously been shown to have any relationship.

The castor bean cake after the oil has been extracted is ground and used as fertilizer. In the process of grinding very fine dust is given off which is carried out through pipes in the roof. The flaxseed, after the extraction of the oil, was still found to contain about 9 per cent of oil and was too heavy for the wind to carry far.

While the odor of linseed oil was quite marked, sensitization tests for castor bean dust and flaxseed dust showed that all those examined reacted to castor bean, and only five to flaxseed, and these in a lesser degree.

In view of the fact that the cause seems so well established, the mill was ordered to take steps to prevent the dissemination of the dust.—*Month. Labor Rev.*, 26:52 (Mar.), 1928.

Quantitative Measurements of the Inhalation, Retention, and Exhalation of Dusts and Fumes by Man: I. Concentrations of 50 to 450 mg. per cubic meter—The purpose of this study was to determine quantitatively the retention of certain representative dusts and fumes by the lungs of persons forced to respire them.

Zinc oxide of a particle size of 0.4 microns, Kadox, which is zinc oxide

having a particle size of 0.15 microns, and marble dust, having a particle size of 0.3 to 6.0 microns were utilized as the representative dusts. These dusts respectively were set up in a 1,600 cu. ft. gas cabinet. The subjects were seated outside of the cabinet and derived their supply of air containing the dust from the cabinet. The quantity of dust which was exhaled was determined by means of an electric precipitator, while the volume of air was found by the use of a spirometer. Concentrations of dust from 50 to 450 mg. per cubic meter were used with exposures of from 5 to 40 minutes and with respirations from 6 to 18 per minute. Under these conditions the percentage retention for all three dusts averaged 55 with a standard deviation of 9.4. This study appears to be a very excellent and accurate piece of work.—P. Drinker, R. M. Thomson, and J. L. Finn, *J. Indust. Hyg.*, 10, 1:13-25 (Jan.), 1928.

L. G.

Changes in the Blood as Reflecting Industrial Damage—The author has reviewed the literature and her own industrial experience with reference to the blood changes on exposure to benzol, toluol, xylol, naphthalene, aromatic nitro compounds, arsine, thallium, and hydrocyanic acids. She finds that a lymphocytosis with the reversal of the leucocyte formula to the lymphocytic side with repression of the neutrophils takes place with the utmost regularity regardless of the particular poison which is acting. This similarity of effect of the various compounds causes the author to look for a common site of action, and leads her to the conjecture that action on the endocrine glands may be taking place since "as a result of functional disturbances of the endocrine glands we have this reversal of the blood formula." Such a hypothesis requires the existence of other signs of endocrine disturb-

ances. These have been suggested by Schmidt in the case of pernicious anemia. "If one admits that a relation between endocrine glands and diseases of the blood is at least conceivable, then it becomes possible to consider damage to the endocrine glands as a means of causation of changes in the blood due to industrial conditions."—Selma Meyer, *J. Indust. Hyg.*, 10, 2:29-55 (Feb.), 1928.
L. G.

Metal Fume Fever: V. Results of the Inhalation by Animals of Zinc and Magnesium Oxide Fumes—The purpose of these experiments was to determine if it was possible to produce a characteristic reaction due to the inhalation of freshly generated zinc oxide in animals, and also to determine whether such a reaction could also be caused by magnesium oxide fume. The authors of this paper have previously shown that it was possible to produce such symptoms in man by the inhalation of zinc oxide.

Accordingly, 25 animals of different species (cats, rabbits and rats) were exposed to freshly generated zinc oxide in an atmosphere of air plus 10 per cent carbon dioxide (in order to increase the depth of respiration) for a period of from 15 minutes to 3¼ hours, and 6 cats were exposed to an atmosphere of freshly generated magnesium oxide.

These experiments disclosed the fact that in the case of zinc oxide the animals displayed a fall in body temperature of slight and fairly transient character following brief exposure, but of marked character and prolonged duration in those animals inhaling the fumes for 1 hour or more. In the case of magnesium oxide a similar but milder reaction was found to result.

The experiments also showed that the amount of zinc inhaled is proportionately much greater during the first part of the exposure and appears to fall off in rate during the later portions of

exposure; and that inhaled zinc oxide is rapidly removed from the lungs of exposed animals, the concentration in the lung decreasing and the concentration in the liver, gall bladder, bile, kidney and pancreas increasing with time.—K. R. Drinker and P. Drinker, *J. Indust. Hyg.*, 10, 2:56-70 (Feb.), 1928.

Chronic Benzol Poisoning Among Women Industrial Workers: A study of the women exposed to benzol fumes in six factories—The author studied the incidence of chronic benzol poisoning among women exposed to the inhalation of this substance in six factories in the State of New York. Complete histories and clinical studies were made on each worker. The criterion of benzol poisoning adopted by Dr. Smith was a history of exposure and a reduction of 25 per cent or more in the white blood cell count. One out of every three women exposed was found to be chronically poisoned by benzol. The susceptibility appeared to be equal among the older and younger workers. There also appears to be a tendency toward a slight increase in the number of basophils as well as an increase in endotheliocytes and the presence of myelocytes.—A. R. Smith, *J. Indust. Hyg.*, 10, 3:73-93 (Mar.), 1928.

L. G.

Efficient Exhaust Systems for Lead Melting Pots in Electrotyping Plants—Sheet metal hoods generally in use for lead melting pots are not so efficient as desired, as they do not afford complete protection for workers standing constantly over the pot, since the fumes must pass the face of the worker in getting to the hood. Lateral suction is recommended in these cases. The apparatus consists of a plate and hood at one end of the pot, the same width as the pot, leading to a pipe and exhaust fan above. The size of the equipment de-

pends upon the size of the pot. This arrangement is much more effective than the old. (Diagram accompanies article.)—John F. Grant, Inspector, *Ind. Hyg. Bul.* N. Y. State Dept of Labor, Dec., 1927.

Apparatus for Artificial Respiration: The Barospirator of Professor T. Thunberg—Probably one of the oldest methods for resuscitation is that of mouth to mouth insufflation. Then followed the mechanical method of blowing air into the lungs and sucking it out for expiration. The manual methods of Silvester and Schafer utilize no apparatus, but simply pressure on certain portions of the body in an effort to perform air exchange in the lungs. The Henderson-Haldane apparatus attempts to stimulate respiration by the stimulatory effect of carbon dioxide on the respiratory center.

The barospirator of Dr. Thunberg consists of an air tight apparatus in which the patient is placed, connected to a large cylinder in which, by the movements of a piston, the pressure is alternately increased and decreased. By this means pressure changes are caused to take place in the lungs, thereby stimulating normal respiration. "The situation is different from that presented by other methods of artificial respiration in that ventilation is attained without volume changes in the pulmonary air spaces."

The majority of persons placed in the barospirator soon lose respiratory movements as the setting of the instrument reaches the proper point. There are no subjective symptoms other than those noticed from the ears. The author concludes that this system offers no danger to the patient, and that an instrument of this type with its undoubtedly high efficiency is bound to find hospital use in due time.—Cecil K. Drinker, *J. Indust. Hyg.* X, 1:7 (Jan.), 1928. L. G.

FOOD, DRUGS AND NUTRITION

WALTER S. FRISBIE

On the Existence of Two Active Factors in the Vitamin B Complex II—Literature is quoted to show that vitamin B is of complex nature containing at least two active substances, one which prevents the onset of experimental beriberi but is not capable of inducing growth when it is the sole addition to a vitamin B-free diet; the other is impotent as a beriberi prophylactic and is also in itself inactive as a growth accelerator but is an essential accessory of the beriberi preventing factor in supporting growth. The former is identical or associated with the pellagra preventing (P-P) substance of Goldberger. The beriberi preventing substance is termed B-P. Both factors were adsorbed by fullers' earth, B-P under certain conditions more than P-P. A combination of treatments with small amounts of fullers' earth, of fractionation with alcohol and of heating, furnished a preparation from an extract of velvet bean leaves, that retained marked properties of preventing pellagra-like symptoms and also of accelerating growth when fortified with sufficient B-P. The treated preparation alone did not produce any growth and did not prolong the life of rats beyond the average on the basal diet alone. A relation between the amount of B-P factor available and the rate of growth was found to exist. The concentration of the B-P factor in a sample of dried kudzu leaves was too low to permit of a complete utilization of the P-P factor.—W. D. Salmon, N. B. Guerrant, and I. M. Hays, *J. Biol. Chem.* 76:487 (Jan.), 1928.

A Study of the Nitrogen Minimum. The Effect of Sixty-three Days of a Protein-free Diet on the Nitrogen

Partition Products in the Urine and on the Heat Production—The constant protein intake of a normal man was made so small as to be negligible by a protein-free diet and when the urinary N excretion was reduced to the so-called N minimum thyroxin (7 mg. intravenous) was administered. The diet was largely sugar (usually sucrose) and cornstarch (1800 calories) with sources of vitamins, roughage (lettuce) and mineral salts. The minimal excretion of total N during a 30-day period before thyroxin administration was 2.10 gm. in 24 hours. In a second 11-day period on this diet following thyroxin the N excretion was lowered to 1.79 and 1.75 gm. on the last two days. The value 1.75 gm. represents 0.0241 gm. per kilo. No noticeable deleterious effect followed the loss in the urine of 259 gm. of deposit protein N which totaled probably 291 gm. of N if amount probably lost in feces be added. The quantity of reserve or deposit protein is much larger than generally believed. The excretion of small quantities of N is not necessarily indicative of a great reduction in the quantity of deposit protein at least in the sense that the body cannot continue to maintain itself for a further period on a N-free diet. The output of creatinine and uric acid as well as neutral sulphur and ethereal sulfate remained extremely constant. The fluctuation in total N was almost entirely due to variations in the amount of urine excreted. The true endogenous metabolism in case of a normal adult man is slightly less than 1 gm. daily. There was a rapid fall in the basal metabolic rate during the first eight days of protein-free diet which occurred coincident with the rapid decrease in the free utilization

of the deposit protein. It remained practically constant when N excretion fell to lower levels and was definitely elevated above normal when the subject was on a high protein diet replenishing his stores of deposit protein. No noticeable physiologic disturbances resulted from the prolonged ingestion of protein-free food other than nausea due to monotony of the food toward the end.—Harry J. Deuel, Jr., Irene Sandiford, Kathleen Sandiford, and Walter M. Boothby, *J. Biol. Chem.* 76:391 (Jan.), 1928.

The Effect of Thyroxin on the Respiratory and Nitrogen Metabolism of a Normal Subject Following Prolonged Nitrogen-free Diet—A reduction of the deposit protein equivalent to 149 gm. of nitrogen by a preliminary period of 30 days on a non-protein diet did not in any way alter the characteristic effect of thyroxin on the nitrogenous or respiratory metabolism.—Harry J. Deuel, Jr., Irene Sandiford, Kathleen Sandiford, and Walter M. Boothby, *J. Biol. Chem.* 76:407 (Jan.), 1928.

Yellow Cocci in Dairy Products Which Survive Pasteurization—In investigations of various dairy products it was observed that yellow colonies of cocci were frequently encountered. These colonies seemed especially numerous on plates from pasteurized products. In the studies of these organisms the resistance to heat, the variations that occur and the general action on milk were given the most attention. Experimental data show that these organisms can resist the usual pasteurization exposures and that the same general resistance to heat was encountered in different materials. Based on cultural studies the authors have suggested a division of these bacteria into three types—A, B and C. A consideration of the various classifications studied suggests that Type A should be considered

Sarcina lutea, Type B as *M. varians*, and Type C as *M. luteus*. The authors further conclude that these organisms were less resistant in milk containing acid sufficient to cause coagulation than in normal milk. They produce changes in milk only slowly and accordingly are probably of little practical importance in the deterioration of dairy products.—B. W. Hammer and G. Malcolm Trout, *J. Dairy Sci.* 11:18 (Jan.), 1928.

Experimental Bone Marrow Reactions. IV. The Influence of Liver and Meat Diets on the Bone Marrow and the Regeneration of Red Blood Cells and Hemoglobin—An experiment was conducted to determine the effect of liver and meat feeding on the blood regeneration of pigeons which were made anemic by starvation. The pigeons were starved from 7 to 13 days after which they were fed: (1) mixed grain diet obtained in the market and used as stock pigeon feed; (2) broiled beef liver, medium done to rare, cut in small pieces by hand to avoid loss of juices; (3) broiled beef muscle treated as liver. The weight of pigeons fed on the grain diet was regained in from 11 to 24 days while beef liver caused a rapid regeneration of red blood cells and hemoglobin up to the 12th day when they began to steadily decline. Beef meat was as effective and in many instances more effective than the grain diet. It was found that mixed grain diet and beef muscle showed essentially the same features with regard to replacement of weight and regeneration of red blood cells and hemoglobin. The bone marrow showed an abundance of erythrocyte formation and a great many megaloblasts. The bone marrows of the liver fed animals up to the 12th day were practically the same as those of the grain and meat fed pigeons. The cholesterol in the serum of the liver fed birds was increased to five times its normal value. The hypothesis is considered that the suppression of red blood

cell and hemoglobin formation is due to the excess of some inhibitory substance in the liver and not to a lack of substances, and it is suggested that the factor of inhibition or suppression of blood formation may be the beneficial factor in the liver diet treatment in pernicious anemia.—Gulli Lindh Muller, *Am. J. Physiol.* 82:269 (Oct.), 1927.

The Effect of Variations in the Proportions of Calcium, Magnesium and Phosphorus Contained in the Diet—It was deemed of considerable importance to determine whether variations in the intake of mineral salts are capable of disturbing the physiological balance among the mineral ions in the tissues to such an extent as to affect the normal functioning of the animal body. Experiments dealt primarily with the effect on rats of variation in the proportions of Ca, Mg and P contained in rations intended to be reasonably adequate in other respects. The general trend of the results obtained leaves no doubt concerning the correctness of the belief that a more or less balanced condition of Ca, Mg and P salts of the ration is essential to normal growth and functioning. High Mg as a disturbing factor in nutrition is definitely indicated by the data on growth and mineral balance, the extent of this disturbance being conditioned by the intake of Ca, P, and vitamins (or their carriers). The response of various groups of animals to certain vitamin levels points to even more important vitamin-mineral interrelationships than have heretofore been recognized.—J. R. Haag and L. S. Palmer, *J. Biol. Chem.* 76:367 (Jan.), 1928.

Vitamin Synthesis in Plants as Affected by Light Source—Biological studies were conducted for vitamins A, B and C in seeds of wheat and yellow milo maize germinated in the dark, in sunlight, and under glass of various

colors, as well as under the mazda, arc, and ultra-violet lamps. The amounts of vitamin A found in seedlings seems to be a factor depending upon the light rather than upon changes taking place in the process of germination. Some increase is always found in etiolated seedlings. The quantity of vitamin A synthesized is dependent upon the intensity of illumination, length of exposure, and evidently the relative amount of shorter wave-lengths, and follows closely the rate of growth of the plant. Vitamin B is evidently not increased in the germination and early growth of the seedlings, its formation coming at a later period of development of the plant. Vitamin C is formed more rapidly than either of the other vitamins studied. There is evidence that germination alone even in the dark, produces a considerable amount of vitamin C. It increases in light-grown seedlings to an extent that is greater than can be accounted for on the basis of the increased growth of the seedlings, and its production is evidently accelerated like vitamin A, by increased intensity of light. Evidence is furnished that plants grown in the open sunlight under intense illumination should be slightly superior sources of vitamin.—V. G. Heller, *J. Biol. Chem.* 76:499 (Jan.), 1928.

Growth Upon Diets Practically Devoid of Arginine With Some Observations Upon the Relation of Glutamic and Aspartic Acids to Nutrition—The relation of arginine to maintenance and growth has been the subject of several investigations none of which has yielded convincing results. The chemical similarity of ornithine and glutamine, the latter probably being the form in which glutamic acid occurs in proteins, is very striking and suggestive. If the animal organism possesses the ability to reduce the acid amide group of glutamine to the methylene amine group of ornithine, a synthetic origin

of arginine might be readily accounted for. White rats were fed three diets; two contained hydrolyzed casein, were practically devoid of arginine, and low in glutamic, hydroxyglutamic and aspartic acids and in the third the nitrogenous element consisted of hydrolyzed casein, containing the three dibasic acids, but had been treated for the removal of arginine. The results point strongly to the conclusion that arginine is not an essential component of the diet. This conclusion is largely possible because of the fact that arginine is probably removed completely as a salt of flavianic acid (2, 4-dinitro-1-naphthol-7-sulfonic acid). The sodium salt of flavianic acid is the coal-tar dye "Naphthol Yellow S." No definite conclusions are drawn on the importance of glutamic and aspartic acids.

Rapid growth can be secured upon diets not only practically devoid of arginine but also low in glutamic and aspartic acids. It is evident that the dibasic amino acids if they are necessary dietary components, the amounts required for growth are very small as compared with the quantities ordinarily present in a casein ration.—W. Edward Bunney with William C. Rose, *J. Biol. Chem.* 76:521 (Jan.), 1928.

Typhoid Fever Epidemic, Santa Ana, Calif.—Following a severe rain-storm December 27, 1923, there occurred an outbreak of a gastrointestinal malady in epidemic proportions. The onset was severe and acute. Out of a population of 27,000, approximately 10,000 were affected, disrupting the activities of the entire city. Many of the attacks were of short duration, lasting one or two days, while the others were more prolonged, ultimately terminating in typhoid fever. The laboratory findings during the first week of the epidemic indicated that the gastrointestinal disturbance in the cases examined were due to bacillary dysentery, a few para-

typhoid cases, and many cases of non-specific gastroenteritis infection. Suspicion was directed to the water supply, but it was not until one month later that final proof of the contamination of the drinking water was obtained. The results following failure to comply with recommendations to chlorinate the water supply and pasteurize the milk supply are quite obvious. In the period between January and April 1924, inclusive, there occurred 620 cases of typhoid fever, 226 of which were due to water supply pollution on December 27, 1923, and 143 to a second pollution on February 7, 1923. During the first week in March following the second pollution of the water supply, an outbreak of typhoid occurred in the city of Orange, five miles distant from Santa Ana, which was subsequently traced to consumption of milk supplied from a Santa Ana dairy. Two hundred cases resulted from the milk—43 in or near Orange, and 157 in Santa Ana—while 51 cases were due to contact. The milk was probably contaminated by a person infected with the polluted water. There was a total of 48 deaths—case fatality rate of 7.7; 28 deaths were among the water-infected patients, 17 among the milk-infected, 3 among contacts. Of 548 cases examined for release, 29 (5.29 per cent) continued to eliminate *B. typhosus* for more than one month. Nine of these were later released on two negative stool specimens. The remaining 20 (3.65 per cent) were carriers for more than 3 months; 11 continued to eliminate typhoid bacilli for more than 6 months. Persons of the age group 45-54 continued to eliminate typhoid bacilli for a longer period than any other age group. Of 916 food-handlers examined, 17 (1.85 per cent) were found to be carriers, 5 of whom gave a history of previous typhoid. One incubation carrier was found.—Charles H. Halliday and M. Dorothy Beck, *J. Prev. Med.* 2:49 (Jan.), 1928.

The Content of Vitamins A and C in Watercress—In determining vitamin A in watercress, rats weighing 45-55 gm. were given a vitamin D-free basal diet, consisting of caseinogen "vitamin free," rice starch, hardened bean seed oil, yeast extract, lemon juice and salt mixture. One litter of 6 rats, weighing 44-49 gm. were given a basal diet containing an ample supply of vitamin D. It was found that watercress is a remarkably rich source of vitamin A, 0.1 gm. only being necessary to promote normal growth. Its growth-promoting properties were found to be stronger in the spring and summer than in the winter. It was also found to contain small amounts of vitamin D. In determining vitamin C, guinea pigs, weighing 200-220 gm., were given a basal diet of ground oats, skimmed milk powder, butterfat and sodium chloride and in addition measured amounts of watercress shoots fresh daily. It was found that watercress is a very rich source of vitamin C, 1 gm. daily being enough to protect the animals for a period of 70 days.—Katharine H. Coward and P. Eggleton, *Lancet*, 1:97 (Jan. 14), 1928.

The Relative Content of the Fat-Soluble Vitamins A and D in a Series of Cod Liver Oils—In examining a series of cod liver oils in preparation of a report on the comparison between colorimetric and biological method in determining vitamin A, the oils were studied for their content of vitamin D to see whether any relationship existed between this and vitamin A present, in any one oil. Vitamin A was determined biologically on young rats. It is concluded that so great a variation in the individual rats precludes the determination of vitamin A with reasonable accuracy unless an inordinate number of rats are used. Tables are given

in which the oils are graded according to the growth increments on 6 and 19 mg. daily doses. Vitamin D was determined by three methods: (1) By increase in bone calcification after small doses for young rats on special diets; (2) by the determination of the lowered ash content in the bones of animals on a special diet "F" described; (3) by the increase in body weight. In spite of the difficulties in making accurate comparisons in biological methods, the authors conclude that the content of vitamin A in cod liver oil bears no relationship to that of vitamin D which is explained by the fact that A is less stable than D and more likely to be affected by heat and oxidation. It is pointed out that the medicinal value of cod liver oil depends more upon the antirachitic value than the content of vitamin A and since these vitamins bear no relationship, the biological method of testing cod liver oil outlined in the U. S. Pharmacopoeia is criticised.—Joan Leigh Clare and Katharine Marjorie Soames, *Lancet*, 1:150 (Jan. 21), 1928.

Is the Antirachitic Vitamin of Cod Liver Oil an Irradiated Ergosterol?—In a brief note the author reports that fractional extraction of the unsaponifiable matter of cod liver oil with alcohol at varying H-ion concentrations yields products of different properties. The extracts at from pH 3 to 5 are pale yellow in color, while with increasing pH the color darkens. The acid extracts give a spectrum identical with that of irradiated ergosterol and are more strongly antirachitic than the alkaline extracts. Other similar properties are noted from which it is inferred that the vitamin is contained in the acid fraction of the unsaponifiable matter.—A. Adam, *Klin. Wchenschr.* 6, 27:1289. 1927. Abstr., *Exper. Sta. Rec.*, 58:90 (Jan.), 1928.

CHILD HYGIENE

MERRILL E. CHAMPION, M.D.

Maternal Mortality in Canada—Report of an Enquiry made by the Division of Child Welfare, Department of Health, Canada, at the request of the First Conference on Medical Services in Canada, held in Ottawa, December, 1924. *Publication No. 37*, Department of Health, Ottawa, 1928. 72 pp.

The information upon which this report is based was collected by means of questionnaires sent to physicians in the Provinces of Canada who signed death certificates of women in the year ended June 30, 1926. These questionnaires were sent in all cases where the recorded cause of death did not clearly eliminate conditions related to childbirth. A large proportion of the physicians concerned responded to the questionnaires, and these replies and the added comments are analyzed in the report, with quotations from many letters. The total number of deaths from causes connected with childbirth was found to be 1,532, a rate of 6.4 per 1,000 live births. The age of the mothers ranged from 15 to 48, the average age being 31. They left 5,073 motherless children, 768 of whom were newborn. In the letters from physicians and others who replied to the questionnaires lack of prenatal care was mentioned more often than any other one factor contributing to these deaths.

The report calls attention to the fact that there is no reason to believe that the number of maternal deaths in the year studied was any greater than in any other recent year, or than it will be in 1928 unless something is done to improve conditions. As remedies the report urges a greater appreciation of the seriousness of this matter on the part of both physicians and the general public, to be brought about by knowledge of the facts and an intelligent and determined effort to reduce the risks of maternity.

The Canadian Division of Child Welfare has issued two new "Little Blue Books" based on this report: *Publication No. 38, Mother—A Little Book for Women*, and *Publication No. 39, Mother—A Little Book for Men*. They explain in simple language the findings of the study and emphasize the importance of pre-

natal care and of proper care during and after childbirth.—

Child Welfare News Summary, Children's Bureau, U. S. Department of Labor, Washington, D. C., Apr. 7, 1928.

Diphtheria Deaths in Massachusetts—The authors comment on the fact that the former gradual drop in the fatality rate of diphtheria has not been apparent in recent years, but that there has been a spectacular drop in the incidence in the past few years. The relative incidence in the school group (6-14) has been decreasing, suggesting that the use of toxin-antitoxin in school clinics is playing an important part in the decrease of the disease.

None of the cases had ever been actively immunized against diphtheria. This is a strong point of immunization.

Two-thirds of the deaths occurred among those of "poor" economic circumstances; 5.5 per cent of the cases had no physician during their illness. The source of infection was known in 19.2 per cent of the cases.

In the "good" economic group, half of the cases had been seen 2 days after the onset, in the "fair" group, half of the cases had been seen 2½ days after the onset, and in the "poor" group, it was over 4 days after the onset before half of the cases had medical attention.

Medical consultation was had in 29 instances.

The foregoing figures indicate very strikingly one of the chief reasons for the continued mortality from this disease. While the too general delay in calling a physician for all manner of illness is well known and regrettable, it is, of course, especially disastrous in the case of diph-

theria where each day's delay in the administration of antitoxin may mean a preventable death. The fact that 68 per cent of the deaths were classed as among the "poor," further indicates the probable complicating factors of economic condition and ignorance.

In only 5 per cent of the cases did the physician fail to make a diagnosis of diphtheria. About half of the cases were of the pharyngeal type, another third laryngeal, while less than 1 per cent were nasal only. The others were combinations of these types. The most frequent complication was of the heart.

About two-thirds of the cases were hospitalized. The average dose of toxin-antitoxin was about 40,000 units.—F. C. Forsbeck & Edward A. Lane *New England J. Med.*, Mar. 1, 1928.

The Non-Tuberculous Child—Non-tuberculous chest diseases require for therapy the identical three factors, rest, food and air, which are being recommended for tuberculous conditions. The present knowledge of these diseases has brought forth rest as the most effective treatment, not only in the case of the adult but also in that of the child. Food, adequate in kind and amount, with the proper eating habits is of secondary importance. A child at rest will partake of his food more heartily and willingly than one fatigued; hence, the close correlation between rest and diet. Air, which in the past has occupied the position of greatest emphasis, has now been shunted to third.

The fears of anxious mothers who suspect pulmonary tuberculosis in their children, because of certain conditions, have been found to be groundless in many cases. The disturbing symptoms reported by parents and which cause them to have the child examined are as follows: (1) underweight, with or without fatigue and listlessness; (2) persistent cough; (3) persistent low grade temperature slightly above normal; (4)

fever remaining after an attack of pneumonia; (5) positive Pirquet test or roentgen ray diagnosis; (6) exposure to open tuberculosis.

Before submitting a definite diagnosis of tuberculosis, each one of these possible symptoms presented should be minutely investigated with a question as to probable causes and significance. An underweight condition does not necessarily denote a tuberculous infection nor does normal weight exclude tuberculosis. Dr. Branneman feels that the greatest coöperation must be given when a child has been exposed to the disease itself.—Joseph Branneman, M. D., *J. A. M. A.*, 90:8 (Feb. 25), 1928.

Public Health Aspects of Heart Disease—In *The Public Health Nurse*, Hart discusses the various phases of cardiac disease from the point of view of the public health worker. He feels that the layman has now become so interested in the question that he wants to know what can be done about it.

Pointing out that mortality is not the only problem in heart disease, he calls attention to the high morbidity, the magnitude of which is known only to those coming into close contact with large numbers of cases. It is not the actual loss of life that constitutes the greatest drain on the community but the number of people, young and old, who are handicapped for life by the results of heart disease. Cohn is quoted as concluding that for every person dying of heart disease, there are 100 living with defective hearts, figures which on a national basis would give approximately 2,000,000 individuals with heart disease.

The causes of heart disease are summarized under three headings: (1) general infections such as diphtheria, rheumatism, syphilis; (2) certain poisons, such as lead; (3) degenerative diseases of middle and late life. Figures seem to show that more than half the cases are the results of infection and

Hart considers this a clue to the direction our preventive measures should follow.

Discussing prevention, the writer touches on the need of effective treatment for syphilis, the need of making use of every possible bit of information regarding the prevention of rheumatic fever, and the need of general hygienic measures to postpone as long as possible the period of growing old. The value of periodic health examinations is stressed as is the importance of cardiac clinics; of convalescent homes for patients with rheumatic fever and with decompensated hearts; of vocational guidance of cardiacs; and of a program of education of the public.—T. Stuart Hart, M. D. *Public Health Nurse*, Mar., 1928.

An Analysis of Anorexia—The fact that liver has been found so efficacious in the treatment of pernicious anemia by the regeneration of blood which, in turn, is demonstrated by the return of appetite, led to a study of the effect of a liver diet on children between the ages of 1 and 14 years who were suffering with anorexia or loss of appetite. Only those children who definitely presented signs of malnutrition in addition to the loss of appetite were considered.

Cases of anorexia may be due to organic defects or purely functional causes. Among the most common organic causes were found to be septic tonsils and adenoids, acute infections, tuberculosis and pyelitis.

In the determination of the treatment of functional anorexia, found in about one-third of the group, three methods were tried: (1) daily use of saccharated

iron; (2) daily use of cod liver oil; (3) addition of fresh calf's liver, broiled beefsteak and lamb's kidney to the diet three times weekly.

No comparison could be drawn between the effects of saccharated iron and cod liver oil but the results of these two were compared with the results of the liver, beefsteak and lamb's kidney feeding. Because with the addition of liver, the increase in weight was considerably greater than with the addition of cod liver oil or saccharated iron, it was concluded that liver may contain a specific stimulant to the appetite.—Walter M. Bartlett, M.D., *Am. J. Dis. Child.*, Jan., 1928.

Home Economics in High School—According to *American Child Health News*, the Manual Arts High School in Los Angeles, has tried the experiment of giving a course in home economics for boys. The latter apparently became interested in home economics for cosmetic reasons because of the general prevalence of acne. After looking into the matter of home economics they acquired a further interest in the preparation of food, and so a class was formed to teach the boys the principles of nutrition and diet. Later, cooking was added.

The final result was that a complete course was worked out for boys for the last two years of high school. An interesting result of this course from the point of view of the health educator was that the boys not only followed the proper dietary regulations themselves, but insisted on their families doing the same.—*Am. Child Health News*, Feb. 7, 1928.

PUBLIC HEALTH NURSING

MIRIAM AMES, R. N.

Baroness Sophie Mannerheim—Nurses throughout the United States and Europe are paying tribute to one of the greatest members of their profession. The death of Baroness Sophie Mannerheim in January of this year, brought to a close a long career of usefulness and service which exerted a widespread influence.

Baroness Mannerheim was born in Finland and educated in the Nightingale School, St. Thomas' Hospital, London, from which she was graduated in 1902. Two years later she returned to Finland to occupy, one after another, positions of importance. She was a moving force, whose wisdom in guidance affected the progress of nursing in her native land.

Her interest in other countries was manifested by her connection with the League of Red Cross Societies, her participation in the activities of the I. C. N. for many years, first as President, and later as Honorary President of the Council.

The nurses who attended the Helsingfors Conference in 1925 have an unforgettable memory of Baroness Mannerheim.

The Biennial Meets in Louisville—Will you be one of the 7000 nurses who will attend the Biennial Convention of the Three National Nursing Organizations, June 4-9, in Louisville, Ky.?

Headquarters for the convention will be in the Jefferson County Armory where the large general meetings will be held, and where a commercial exhibit of about 100 displays of interest to nurses will be conducted.

Dr. Charles Hubbard Judd, head of the School of Education at the University of Chicago, will be the speaker at

the opening meeting of the convention, June 4, at the Armory, his subject being "Adult Education." Convention members will be welcomed at this time by the Governor of Kentucky and the Mayor of Louisville, who will speak; and S. Lillian Clayton, President of the American Nurses' Association, will respond for the nurses. Brief talks will be given by Miss Clayton, Carrie M. Hall, President of the National League of Nursing Education, Anne L. Hansen, President of the National Organization of Public Health Nursing, and Clara D. Noyes, director of the Nursing Service of the American Red Cross.

Municipal Nursing Session will be held June 6, from 11 to 1 o'clock under the auspices of the N. O. P. H. N. The subject will be "Appraisal of Municipal Nursing Service," (a) "Tools for Measuring Nursing Service," discussed by W. F. Walker, D. P. H. of the A. P. H. A., and (b) "Factors Determining the Scope of the Nursing Program," by Emma Winslow, Ph.D., of the Commonwealth Fund.

There will be sessions on rural, school, tuberculosis and industrial nursing; on staff education and supervision; on relationships between community chest and public health nursing organizations.

Supervised Midwifery Versus ———?—Many Americans resent the insinuation that practices in their country are inferior to those abroad. Yet the low maternal mortality in certain European countries which have supervised midwife practices at least makes us question our own maternal mortality and our attitude on the subject of midwifery.

Scandinavia is one of the countries which has a system of supervised midwifery. Schools where midwives are trained are aided by government subsidies and are parts of large maternity hospitals. Here, girls who are recruited from the classes which would furnish student nurses in this country, receive a thorough training by means of practice and precept. They are trained to realize that childbearing should be a perfectly normal function but that abnormal conditions may develop, when a doctor is necessary. Therefore, they are taught to recognize these abnormalities. In the one or two years of training, ample opportunity is given for actual assistance in childbirth, as many as 80 or more cases being attended each year by each student under supervision.

Because most of the midwives or "maternity nurses" in Sweden go into rural communities where doctors are not readily reached, these women are taught certain obstetric operations. They are also taught to give prenatal advice and information about the general hygiene of the normal child in its first year.

Each midwife makes a report of her work periodically to a central authority. Additional requirements are that she take review courses of two weeks each at certain intervals and must retire at the age of 50. The results of this careful training and supervision may be judged in part by the low maternal death rates and the morbidity following childbirth.

While the Scandinavians are a homogeneous people and their physical development favors natural labor, yet they have the same sort of complications of pregnancy as exist in our country. However, proportionately there are not so many cases of sepsis as in the United States. Does the low maternal mortality and morbidity from sepsis in Scandinavia and the high maternal mortality and morbidity from the same disease in the United States indicate the

necessity for encouraging a similar system of midwifery in our country? Even in the United States, the midwife has been "credited with better results as far as sepsis is concerned than has the physician." But the haphazard way in which this practice is carried out in most parts of the United States demands a reform if this type of medical practice is to continue.

While there may be some objections to recommending supervised midwifery unreservedly in the United States, some solution of our high maternal mortality must be found by the medical profession.—George W. Kosmak, M.D., Results of Supervised Midwife Practice in Certain European Countries, *J. A. M. A.* 89, 24: 2009 (Dec. 10), 1927. B. J. B.

Scarlet Fever Review—Although we may be sure of our knowledge, an occasional review of the facts, especially when these facts are presented by an authority, is advantageous. Therefore, we are glad to have Dr. Dyer's summary of scarlet fever.

Occurrence—In the United States, scarlet fever is more prevalent in the North than in the South. It occurs during the cold months of the year, the peak being reached in December and January.

Susceptibility—Scarlet fever is primarily a disease of childhood, although it may attack persons of any age. Between 2 years and 9 years, children are most apt to catch the disease and the fatality is greatest.

Cause—Hemolytic streptococci are now regarded as being the cause of the disease. The germs are found in the throats of scarlet fever cases and their transference to the throats and nasal passages of susceptibles, either directly or indirectly, causes the disease, in others. Bodily discharges are also infective. Like the diphtheria germ, scarlet fever germs not only cause a local reaction but also produce a poison which is absorbed by the body.

The Disease—There are three well established stages in scarlet fever: (1) period of infection; (2) period of eruption; (3) period of desquamation. In the first, the child becomes suddenly ill with sore throat and fever, often with vomiting. The tongue is furred and throat parched. This stage usually lasts 24 to 36 hours.

The eruption, usually appearing on the second day, may come out a few hours after the first symptom or it may wait for 48 hours. It appears first on the neck and chest and readily spreads over the entire body. This may persist for 2 or 3 days and then gradually fades, accompanied by a decrease in temperature.

The amount of peeling usually depends upon the intensity of the rash. Desquamation usually lasts from 10 to 20 days.

The severity of the symptoms depends upon the type of the disease. The tongue in scarlet fever has a characteristic appearance. At the outset, it is coated with white, the edges being red. The papillae appear as little red points. Later, the coating disappears leaving the tongue rough and red, the characteristic "raspberry tongue."

Inflammation of the throat is likewise a prominent symptom in scarlet fever.

Complications—The most common complications are inflammation of the kidneys, middle ear disease, endocarditis, adenitis, and joint affections. These may follow even apparently mild cases of scarlet fever.

Period of Communicability—Scarlet fever can be transmitted from the time of onset until the infectious agent has disappeared from the mucous membrane and from any discharges. In most uncomplicated cases, it is probably not infectious in the 4th week of an attack.

Carriers—Carriers in scarlet fever are persons with such slight cases that they are not known to have the disease, and convalescents who harbor the germs.

Prevention—The Dick test has been devised to determine susceptibility to scarlet fever. In this, a small amount of scarlet fever streptococcus toxin is injected into the skin. Susceptibility is shown by the presence of a reddened area, appearing in about 24 hours at the site of injection. Larger amounts of scarlet fever toxin may be given to susceptible persons to give them immunity (now five doses at weekly intervals are given). This method of immunization is especially useful in institutions and to protect nurses caring for scarlet fever patients.

Care of Scarlet Fever Patients—A patient should be carefully isolated. All but necessary furniture should be removed from the room where he is. Everything in contact with the patient should be cared for by itself, whether bedding, towels, eating utensils. After use, they should be kept an hour or two in disinfectant solution or boiled in soapsuds. Partially eaten food should be burned. Cloths or paper napkins, soiled with discharges from the patient, should be burned.

Precautions for the Attendant—As the hands

of the attendant may become readily infected in the care of the scarlet fever patient, unnecessary handling of the patient should be avoided. When contact is necessary, the hands should be cleansed in hot soapsuds. The attendant should also protect herself by covering hair and clothing. The coverings should be disinfected before being sent out of the room.

Disinfection—This is governed by the regulations of the local board of health. Gaseous disinfectants are probably useless. More effective is thorough cleaning of the room with soap and water and the action of fresh air and sunlight.

Treatment of Contacts—If scarlet fever occurs in a family of children, it does not necessarily follow that all the children will have the disease, especially if isolation is prompt and complete. Such contacts, if possible, should be sent away to relatives or friends having no small children. There they should be carefully watched for symptoms indicating the presence of the disease. They should be kept from school during this period. Adult members of the family, taking precautions and avoiding any contact with the patient, may come and go freely, except in the case of food handlers.

Many contacts may be protected by immunization with scarlet fever toxin (after a preliminary Dick test). When the test is given, cultures from the nose and throat should be made to determine presence or absence of the hemolytic streptococcus. If the test shows susceptibility and if there are no symptoms of scarlet fever (such as, temperature or sore throat), the first immunizing dose of toxin may be given. An exposed child with positive Dick test and harboring scarlet fever germs should be watched and should not be given further injections of toxin if symptoms exist. An exposed child with positive Dick test and symptoms of scarlet fever may be given an early therapeutic dose of scarlet fever antitoxin.

Precautions—The case should be reported immediately and all quarantine regulations strictly observed. A food handler in whose household scarlet fever occurs should discontinue business while scarlet fever remains on the premises. Even then, he should stay away from work until time has shown that other members of the family have escaped infection. Milk bottles, before leaving the house, should be thoroughly disinfected, and should not come into contact with the persons caring for the patient.

Control—Teachers, school nurses, and school doctors, can do much to control the spread of scarlet fever in schools. The teacher can exclude

from classroom any child appearing ill. Immunization of susceptible persons by the scarlet fever toxin may be used where chances of exposure are greatest. (This toxin has been used too short a time to permit a statement as to how lasting such immunity is.) In cases of deaths from the disease, a public funeral should not be held.

General Precautions Against Catching the Disease—Infections are more apt to be established where there are diseased conditions in the mouth; such as, defective teeth, or diseased tonsils and adenoids. Such conditions, therefore, should be remedied. Also, children should be taught to keep things out of the mouth which do not belong in it.—

Surgeon R. E. Dyer, U.S.P.H.S., Scarlet Fever: Its Prevention and Control. *Pub. Health Rep.*, 43,2:57 (Jan. 13), 1928. B. J. B.

Public Health Nurses, Illinois—The Illinois State Department of Public Health aims to inaugurate a nursing service in every one of the 102 counties of the state. At present 31 counties are without nursing service of any kind. The department has just received an added appropriation providing for an increase of staff from 4 to 15 nurses.—*Weekly Notes on Child Welfare Topics*, U. S. Children's Bureau.

Public Health Nurses, California—Requirements for applicant for examination for certificate as a public health nurse. Adopted by the State Board of Health, October 6, 1923. Amended July 31, 1925. Amended February 4, 1928.

Resolved, that each applicant for examination for certificate as public health nurse shall be:

1. Registered nurse under the laws of California.
2. Shall have completed a public health nursing course of eight months in a school approved by the California State Board of Public Health, or
3. Shall present evidence of having engaged in general public health nursing for at least 2 years in connection with a public health organization approved by the California State Board of Public Health.
4. In addition to the 2 years' practical experience evidence shall be required showing

that the candidate has attended a summer course of at least 6 weeks at the University of California, at Berkeley or Los Angeles, or a course of equal standard at any other university, or

5. In addition to the 2 years' practical experience evidence showing that the nurse has completed a 4 months' course in public health nursing, the outline of which has been approved by the California State Board of Public Health, will be accepted in lieu of the 6 weeks' course in public health nursing at a university.

6. All applications for examination as public health nurse shall be filed in the office of the State Department of Public Health, State Building, San Francisco, and shall be passed on by a committee of the State Board of Public Health.

7. All applications shall have attached to them an affidavit, sworn to before a notary public, as to qualifications outlined in paragraphs 2, 3, 4 and 5.

8. These regulations shall be in force and effect on and after February 4, 1928.—

State of California, *Weekly Bulletin*. VII, 2 (Feb. 18), 1928.

The Nurse's Part in Cancer Control—There is a tendency among those who have cared for patients with incurable cancer to feel that there is no hope where this disease is concerned. Yet research information tells us that one-fifth of the 5,000 persons who die each year from cancer in Massachusetts could have been saved if they had received treatment in time, instead of waiting until their condition was hopeless before securing medical advice.

If this is true for Massachusetts, it is also undoubtedly true for the rest of the United States. Has not the nurse a message of hope when she knows that there should be no skin cancers, that 70 per cent of the breast cancers could be cured if taken in time, and that rectal and also external cancers can be controlled or cured? The nurse can not only aid by urging early examination of superficial cases and prompt treatment, but she can also bear a message to those who are nursed in the home. Perhaps the best she can do for these is to de-

nounce the spending of money for quack treatment. She also can help persons to realize the dangers of the indiscriminate use of morphine which may be taken to alleviate pain.

The nurse can do much to help the cancer patient if she will courageously use the knowledge which is at hand.—Elizabeth Ross, How Can We Help in the Control of Cancer, *Pub. Health Nurse*, XX, 1:13 (Jan.), 1928.

B. J. B.

The Psychology of Keeping Young—Under the guise of this attractive title, a sound lecture in mental hygiene was given by Prof. H. Overstreet of the College of the City of New York at Ford Hall, Boston, Mass., in December.

Of course, it is understood that in a discourse of this kind the words "youth" or "senility" refer not to the physical body, nor to the mind taken as a separate entity, but to the subtle blending of the two which enters into the making of a personality.

However, for the purpose of illustration, he began with the causes of physical senility and debilitation. These were:

1. Poisons—endogenous or exogenous; that is, poisons produced within the body due to organic disorders or poisons introduced from outside, such as bacteria which start up toxic processes as soon as they find suitable conditions in the body.

2. Starvation—due to either the quantity or the quality of the food ingested. Now when we consider the causes of the aging of the "body-mind," we find these same two factors—poisons and starvation. In this case, the poisons are our emotions, those which are frustrated and are not allowed to be expressed either directly or through some other channel. We know how much we can be aided by our instincts and emotions; we are afraid of fire—

therefore, we avoid it. But if we saw fire, were afraid but could not escape, our lives would be endangered. In the same way, worry, anger, sorrow and all the other emotions are undermining if they are allowed to grow to enormous dimensions with no outlet for escape.

As to starvation, senility approach is rapid if we allow ourselves to fall into a rut and give ourselves no new interests. No matter what the physical age is, anyone who keeps abreast of the existing world and develops new interests as the years go by wards off the bugaboo of old age.

After dealing with the causes and prophylaxis of senility, Prof. Overstreet gave the symptoms (a rather irregular procedure but good for the morale of the audience which might have diminished had the process been reversed). The symptoms enumerated were talkativeness or the other extreme of silence, and the practice of reminiscence!

The lecturer made one amusing suggestion. He expressed the opinion that instead of determining a person's I. Q. by an intelligence test, it would be much more valuable to give him a senility test to serve as a warning of approaching danger. That would be the only kind of examination in which the lowest rating would give the highest honor.

H. Z.

(Miss Haigouhy Zouvickian, a staff nurse of the Community Health Association of Boston, is also one of the Editors of the *Community Health News*, which made its first appearance in October, 1927. The bulletin serves to keep the staff nurses informed of interesting phases of public health nursing, and changes in personnel. It is pleasing, both for its serious and humorous content.)—*Community Health News*, Dec., 1927.

EDUCATION AND PUBLICITY

EVART G. ROUTZAHN*

The Cost of a Community Bulletin—The attractive bulletin of the Dutch-ess County Health Association will illustrate the cost of getting out about 425 copies of an average monthly issue of six letter size pages:

When we are able to obtain cuts free of charge (of late we have been able to borrow them from the State Committee on Tuberculosis and Public Health of the State Charities Aid Association) we have the printer print the title and cuts only, for the first and last pages. The news items we multigraph here in our office. When we are unable to secure cuts, we simply multigraph the whole thing in the office, title page and all.

We buy a year's supply of paper (20,000 sheets) at a time, thus getting it more cheaply. Following is a list of the costs:

Paper	\$4.05
Printing (title and cuts)	3.40
Postage (1-½c envelopes unsealed)	6.45
	<hr/>
	13.90

In addition it takes the office secretary approximately one week to address the envelopes, multigraph the letter, assemble, clip, fold, and insert it in the envelopes. Her salary is \$23.00 a week.

It takes me approximately the equivalent of one day's work to get the material in order to print.

Dorothy J. Carter, executive secretary, may be addressed at 16 Cannon St., Poughkeepsie, N. Y.

Health Poster Information—Information about health posters—present and future—is offered by the National Tuberculosis Association. The service starts with a loose-leaf binder containing posters or reproductions of posters, with descriptions and prices from 32 national organizations. Price, \$25. For an additional fee of \$7.50 per year, additions

will be made to the collection from time to time. This service should be of much interest and value to health workers who have thought out the poster situation and have learned how to discriminate between those that are good and those not so good. It is too easy now to secure mediocre posters. May the time come when not one man or one organization will select the posters, but when a representative group will offer a service in which the posters distributed will meet reasonably high standards in conception, text, design and printing.

Statistics in a Window Display—It seems possible to use a simple statistical comparison effectively in a window display. Perhaps you wish to show the downward trend of tuberculosis through a period of years, the upward trend of cancer or heart disease, or the increased use of a health center. The usual bar diagram may be replaced by a group of large cylinders made of colored paper. Add a solid background, say of dark cloth which the store window display man will have on hand. Size of cylinders and their distance from the background will be determined by experiment in relation to the width and depth of the window. Above the cylinders will run a concise caption done in modernistic style. Experiment may show that the caption can be supplemented by reproducing the diagram on a smaller scale on a card, thus making more obvious the larger display by cylinders.

The Nurse Must Know How to Arouse Interest—"She must know how to arouse community interest in a maternity and infancy program, in bet-

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

ter care for mothers and babies. That goes far beyond a mere publicity campaign. It goes into the realm of knowing how to arouse and make use of the latent interest of every group in her community, and by actually tying it into her program, making it come to life and amount to something."—From *Standards for Training of Public Health Nurses*, by Elizabeth Fox.

That means a *real* publicity campaign—and not "a *mere* publicity campaign"! At present it is difficult for the public health nurse to obtain training along these lines.

What Pennsylvania Does—The Bureau of Public Health Education, State Department of Health

. . . prepared 52 weekly health talks which were broadcast throughout the newspapers of the Commonwealth. Items for the *American Medical Journal*, the *Atlantic Medical Journal* and other publications were regularly released, as also were facts of interest to the newspaper reading public. Moving pictures circulated by this bureau for the year 1927 reached a total of 110. *Pennsylvania's Health*, the official journal of the Department, was prepared and issued six times during the year. The journal is now forwarded to 26,000 people, and for the entire year reached 132,000 first readers of all issues published. Campaigns in which this bureau took part involved the annual clean-up week, anti-fly activity. Lancaster welfare drive and Pennsylvania farm show.

Five Steps Leading to Better Health Education—

Of course our printed matter and other educational material can be improved. Five simple, though vital steps to that end were emphasized at the 1927 Public Health Conference called by the American Medical Association:

1. More general use of accepted principles, technics and forms of skill adapted to our needs. I refer especially to the technic of printing, principles of psychology, and facility in writing in every-day language.
2. Employment of persons to do the work of health education who are trained to do it, and this means that we must first offer training.
3. Revision of the methods of supervision

and the working conditions under which preparation of health education material is carried on.

4. A philosophy and a program for the health education work of official and private agencies. Both of these elements are lacking in the work of many agencies.

5. Recognition of the time and thought that is necessary in producing publicity material that gets results.

"Will the Girls Be Interested?"—

When the Girls Work Committee, Chicago Council of Social Agencies, started the "Girls Health Trail" project they had no idea with what enthusiasm the girls would respond.

Interest them in health habits we must, for we were desperately aware that young women living under present conditions of personal liberty and city tension were spendthrifts of health. . . . Could these independent, heedless schoolgirls or these hard working young girls in office and industry be interested in checking up their own health habits by means of a simple daily health chart? Would they submit to the physical examination which might disclose the presence of disease in time to enable them to secure the necessary attention to teeth, eyesight, etc.?

We have our answer. More than 7,000 girls have already agreed to keep the daily habit chart for three months. Our physical examination centers are overworked, even though all girls able to do so are requested to go to their private physicians.

"The Girls' Health Trail," is simply the united simultaneous effort of participating organizations to arouse civic attention to the health programs of individual agencies and to stimulate a more general interest in the health of girls.—

Social Service, Chicago, Ill. For a description of the "Trail to Health" see *Dairy Council News*, 910 South Michigan Ave., Chicago. March, 1928. *Free*.

SLIDES AND FILM SLIDES

The usefulness of the title-slide for lantern slides is emphasized in "The Sub-Title Applied to the Lantern Slide," by J. N. Emery. *Educational Screen*, 5 South Wabash Ave., Chicago, Ill., April, 1928. 25 cents. But of course the text and appearance should be comparable to the best of the screen captions. The

article tells how to utilize discarded photographic negatives, glassine wrappers from candy boxes, as well as the commercially prepared gelatin-mat-carbon combinations.

An example of the services offered by state universities is the slide material on health included in the 1927-1928 catalogue of Lantern Slides of the Extension Division, Indiana University, Bloomington, Ind. *Free*. (Outside of the state \$2 a week rental is charged.)

Film slides or strip films available through the Metropolitan Life Insurance Company, 1 Madison Ave., New York, N. Y., include "No More Diphtheria," "One Scar or Many," "Working for Dear Life," and "How to Live Long" (general health).

NEW PERIODICALS

Tuberculosis Abstracts, National Tuberculosis Association, 370 Seventh Ave., New York, N. Y.: A 2-page review for physicians. *Free*.

Postage has absorbed *The Mailbag*, and will continue publication of the combined magazine at 18 East 18th St., New York, N. Y.

Medical Progress, "a journal for laymen," American Association for Medical Progress, 370 Seventh Ave., New York, N. Y. Quarterly. \$1.00 a year. Sample copy *free*. "To diffuse among the lay public an understanding of research methods in medical science."

Food and Health Education, 468 Fourth Ave., New York, N. Y., has become *The Home Economist*.

Dry News is house organ of American Dry Milk Institute, 160 North La Salle St., Chicago, Ill.

FOR THE NEWSPAPER

The school nurse—Bureau of Education, Washington, D. C. News Release "P. N. 22124."

Preventive treatment for children's teeth—Bureau of Education, Washington, D. C. News release "P. N. 22125."

A series of news releases issued by U. S. Public Health Service, Washington, tell of world progress and national progress in public health. *Free*.

Again the Syracuse *Post-Standard*, in coöperation with the local Department of Health, published an Annual Spring Health Number, a 20 page tabloid magazine section of its March 18, 1928, issue. Samples *free*. Address R. W. Andrews, *Post-Standard*, Syracuse, N. Y.

Material to be worked into copy for bulletins and press releases: "Principal Causes of Illness in a Typical American City." U. S. Public Health Service. Released March 26, 1928.

The latest syndicated newspaper health column is "Health—How to Keep It," by Dr. Herman N. Bundesen. "All reader queries answered personally by mail." A recent week's series covered "Happiness—the Child's Tonic," "Is Your Child Jealous?" "Exercise for Health," "Character Building," "Overcoming Fear," "Mental Habits." Doubtless sample copies will be sent upon request to the Syndicate Department, *Chicago Daily News*, 15 North Wells St., Chicago, Ill.

"The total number of morning and evening dailies in the United States now is 1,949, compared with the previous year's 2,001. The total circulation of our evening papers now exceeds 23,000,000 copies daily; for morning papers the daily circulation exceeds 14,000,000 copies; Sunday total circulations exceed 25,000,000."—*Editor and Publisher*, Jan. 21, 1928.

STATISTICS

The Department of Commerce, Washington, D. C., will supply copies of "Estimates of Population for the United States and States for 1928." *Free*.

A few paragraphs explaining several simple features of vital statistics—in "Vital Statistics Are Interesting," by G. B. L. Arner. *Pennsylvania's Health*, Harrisburg, Pa. March-April, 1928.

BULLETINS

A good grade of envelope, in contrast with the cheaper manila envelopes, now gains a better hearing for *Campaign Notes* of American Society for the Control of Cancer.

The Canadian Red Cross, Toronto, Can., has gained in attractiveness and readability by reducing the amount of red on its pages and adopting a new typography. The contents, also, have become far more interesting and definitely helpful to its readers.

What insurance companies and insurance funds are doing to educate the public in various countries is told in "Insurance and Health Education." *World's Health*, Paris, France, Dec., 1927. 20 cents.

Detailed information about the 15 organizations comprising the National Health Council is given in a directory page of the *Monthly Digest*, 370 Seventh Ave., New York, N. Y. Copy free.

Several popular articles appear in the Special Milk Number of the *Northwestern Health Journal*, St. Paul, Minn. Nov., 1927. 10 cents.

Mental Hygiene Bulletin, National Committee for Mental Hygiene, 370 Seventh Ave., New York, N. Y., has been re-born in appearance and contents. Sample free.

NEWSPAPERS

Again *Editor and Publisher* issues its International Year Book edition with lists of dailies in many countries; city and Sunday editors named for many United States and Canada dailies; numerous classified lists; art and literary markets in the United States; books, schools, syndicates, mat and cut services, etc., 352 pages 10 by 13 inches. Jan. 28, 1928. Times Bldg., New York, N. Y. \$4.00 with year's subscription.

Fair and wise policies in dealing with the newspapers in emergencies are outlined in "Helpful Relations with Local Newspapers," by F. H. Williams. *Trained Nurse*. Oct., 1927. Especially

important are the detailed suggestions as to information to be supplied in writing, and the handling of telephone interviews.

MOTION PICTURES

"Just Around the Corner," is divided into three parts: Dependency, Health and Character Building. The Four Horsemen are brought into the scene of each picture in silhouette, representing Poverty, Evil, Sickness, and Death.

A great city with its tall buildings, shining lights and bridges sleeps under a seemingly calm exterior. Through the sky, riding swiftly, come the Four Horsemen, tramping down the weak, the sick, the helpless and the underprivileged.

The work of the visiting nurses, Infant Welfare Society, Occupational Therapy Department of the Junior Board and summer camps are shown under the section of Health. These agencies beat down the advance of the Horsemen who gallop through the scenes, holding the thrill of the picture.—

Otto Bradley, Community Fund, Minneapolis, Minn.

A film entitled "The Fly Majanka and her adventures" tells the story of an adventurous fly which gains entrance to a library and turns over the pages of a text-book of hygiene. She realizes the damage done by flies and calls a big meeting of flies at which she appeals to them not to settle on human food. The flies laugh at her and chase her away and she takes refuge in a doctor's house. There she turns her attention to the doctor and begs him to start a campaign. She shows him a mill-pond with larvae floating on it, leads him to the "Fly's Paradise," an insanitary rural privy, and altogether reads him a severe lesson. Majanka and her companion at length reach the farm of a peasant named Kluge, a model of cleanliness, who takes all the proper precautions against flies but complains that his efforts are of little avail since his neighbor cares not a rap. The doctor visits the careless neighbor and lectures to him about his dirty cowsheds, telling him the reason of his child's inexplicable illness from an infectious disease. Finally all the neighbors are converted and a great campaign against flies takes place. Every fly is destroyed except the adventurous Majanka, who, as befits one who has made history, is handed down to posterity in a museum!—

Reichsausschuss für Hygienische Volksbelehrung, Luisenplatz 2-4, Berlin N. W. 6.

EDUCATIONAL MATERIAL

The revised series of pamphlets and other publications of the American Heart Association, in course of preparation, have been classified as follows: (a) those for the workers, including physicians, nurses, secretaries and others; (b) those for the patients and their families; and (c) those for the general public.

Health-Diseases, Drugs and Sanitation. List of publications relating to these subjects. Revised. Superintendent of Documents, Washington, D. C. Price List 51. *Free.* New editions mailed as issued—if requested.

Safeguarding Your Health From Tuberculosis. Department of Health, New Haven, Conn. Well done 24-page pamphlet explaining to citizens "How New Haven Cares for Tuberculosis" through public and private agencies. A form of reporting the work being done.

The 50 million dollar welfare bond issue to be voted on in Pennsylvania in November is responsible for four 6-page folders issued by the Pennsylvania Mental Hygiene Committee of the Public Charities Association, 311 South Juniper St., Philadelphia, Pa. The copy is good, and the form is a good example of the better grade of quite inexpensive folder for widespread use. Of course the type should be larger, but the leading makes it quite readable. Each of the series is on a different color of paper. The titles: "Salvaging the Feeble-minded," "Handicaps of Epilepsy," "Why So Many Go Insane," "Do You Know?" Samples *free.*

A handy manual of 16 pages, *Health for the Family*, tells the residents of Bellevue-Yorkville district, New York City, of the clinics and services available. Page by page a type of clinic or service is described, with days and hours. Very well done—except that the

map might better have been an inch wider to gain in clearness and usability. Address Bellevue-Yorkville Health Demonstration, 325 East 38th St., New York, N. Y. *Free.*

An educational campaign against rickets conducted by Mulberry Health Center, 256 Mott Street, New York City, produced a series of exceptionally good 1-page leaflets, an 8-page pamphlet, and four posters (one of which is not so good). A sample set for \$1.50; set of leaflets, 10 cents; posters, 40 cents each. Special rates for quantities. Ask for "Plans for a Campaign Against Rickets." See reproductions in *Trained Nurse*. Jan., 1928. A brief account of the campaign in *Public Health Nurse*, March, 1928.

HONORABLE MENTION

Health, New Hampshire State Board of Health: for list of contents on cover page.

Fifth Annual Report of Quebec Provincial Bureau of Health: for a table of contents (called an index).

REQUESTS

Outline diagrams of the digestive tract are desired by Mabel Milhan, Home Demonstration Agent, Canton, N. Y. Please send your answer also to editor of this department.

Copies of posters and other material, as well as suggestions helpful in preparing a health exhibition will be appreciated by Dr. T. N. Mazumdar, Health Officer, Calcutta, India.

"On the average, what proportion of a welfare or nursing budget do you think might well be devoted to publicity purposes?"

Who has issued a folder or other publication entitled "The Cheapest Health Insurance"?

LAW AND LEGISLATION

JAMES A. TOBEY, LL. B., DR. P. H.

Sunk in committee?—The Jones Bill, S.3356, for federal health coördination has been transferred from the Senate committee on Commerce, of which Mr. Jones is chairman, to the Committee on Finance, of which Mr. Smoot is chairman. As a consequence, many observers believe that this measure will be permitted to repose peacefully there for some time.

As previously announced, the Parker Bill (H. R. 11026) passed the House early in March. When this was sent to the Senate it was referred to the Senate Committee on Commerce, of which Mr. Jones is chairman, where it is expected to receive favorable consideration. Mr. Jones at the same time introduced another bill (S. 3356) which was a counterpart of the Parker Bill. This bill was also originally referred to the Commerce Committee, but Mr. Smoot, Chairman of the Committee on Finance, somewhat belatedly discovered this and asked that Mr. Jones's bill be referred to the Finance Committee. This has been done and Mr. Smoot indicates that this bill will probably not be reported out of his committee. Since the bills are identical, favorable action on the original House bill will provide the desirable legislation for federal health correlation even if the Senate bill is killed in Mr. Smoot's committee.*

Senator Ramsdell has introduced a new bill for a National Institute of Health and this measure, S.3391, now contains none of the provisions for federal health correlation, but merely a proposal for \$10,000,000 for what is virtually a vast expansion of the Hygienic Laboratory.

A Federal Cancer Study—A thorough investigation of the means and methods whereby the federal government may aid in discovering a successful and practical cure for cancer would be made by the National Academy of Sciences, according to a bill, S.3554, introduced in the Senate by Mr. Neely. A report would be made to Congress for a plan for the participation of the federal government in eradicating cancer. In order to perform this task, an appropriation of \$100,000 would be authorized to reimburse the National Academy.

Anti-vivisection—A little late, but none the less offensive, the anti-vivisection bill has finally appeared in Congress as H. R. 11998. Instead of prohibiting experiments upon living canines, this particular measure makes it a misdemeanor for any person to operate or experiment upon a living dog in the District of Columbia or the Territories, except for the purpose of healing or curing the dog.

Oleomargarine Again—Hearings on Senator Norbeck's bill to extend the definition of oleomargarine to include substances churned, emulsified, or mixed in cream, milk, water, or other liquid, and containing moisture in excess of 1 per centum, were begun on March 27, 1928. Representatives of the U. S. Department of Agriculture, the Bureau of Internal Revenue, and various national dairy associations appeared in favor of the bill, while a Chicago lawyer representing the Baltimore Butterine Company, and the E. S. Vail Butteryne Company of Chicago appeared in opposition. He stated that manufacturers of

* For later developments, see page 639.

oleomargarine were back of the bill, the object of it being to eliminate the markets for yellow vegetable oil cooking products.

No money appropriated for the support of any ward, officer, or employe of the United States Government, civil or military, or for any veteran could henceforth be spent on oleomargarine, filled milk, or other alleged substitute for butter or other dairy products, according to a bill, H. R. 12246, introduced in the House by Mr. Sweet.

A bill, S. 3737, relative to the taxing of oleomargarine has been introduced by Senator Tydings.

An Osteopath as Surgeon General—Characterizing it as "a vicious medical practice bill," the *Journal of the American Medical Association* seems greatly alarmed by a measure proposed by the only physician in the United States Senate, Dr. R. S. Copeland. According to this magazine for March 17, 1928, "Osteopath surgeon generals of the Army, Navy and U. S. Public Health Service are a possibility if a bill (S. 3592) introduced in Congress by Senator Copeland, March 10, becomes a law." The bill of the Hon. R. S. Copeland, M.D., provides that the degrees of doctor of medicine and doctor of osteopathy shall be accorded the same rights and privileges under governmental regulations, whatever this phrase means.

A proposal to regulate osteopathy in the District of Columbia, H. R. 16, was favorably reported to the House on March 28 and discussed at length in the House on April 9, though without action other than talk.

The chiropractors have also received some recognition from Dr. Copeland, for at hearings on a medical practice bill for the District of Columbia before a subcommittee of which he is chairman, Senator Copeland agreed to the contention of these cultists, supported by Senator

Capper, that they should have a separate examining board, mentioned by name in a medical practice bill for the District.

Honors for the Heroes of Health—Recognition for the survivors of the famous yellow fever experiments in Cuba and also for the wives of those concerned who have died is contained in bills submitted to Congress, in the House by Mr. Wainwright as H. R. 11686, and the Senate by Dr. Copeland as S. 3364.

The persons whose names the War Department would be directed to place on its roles and pay \$250 a month are as follows:

Mrs. Walter Reed
Mrs. James Carroll
Mrs. Jesse W. Lazear
Dr. Aristides Agramonte
Pvt. John H. Andrus
Mr. John R. Bullard
Pvt. A. W. Covington
Pvt. William Dean
Pvt. Wallace Forbes
Pvt. Levi E. Falk
Pvt. P. Hamann
Pvt. James F. Hanberry
Mrs. Warren G. Jernegan
Pvt. John R. Kissinger
Mr. John J. Moran
Pvt. William Olson
Pvt. Charles G. Sonntag
Pvt. Clyde L. West
Dr. R. P. Cooke
Pvt. Thomas M. England
Pvt. James Hildebrand
Pvt. Edward Weatherwalks

The bill also calls for a National Honors Commission of seven who would investigate all cases of distinguished service of public servants by voluntary risk of life or health and recommend proper recognition for such service.

On March 15 the House passed a resolution to change the name of the Ancon Hospital in the Canal Zone to the Gorgas Hospital.

Gorgas Memorial Laboratory— Apparently without a dissenting voice and amid lavish praise for General Gorgas, the House on March 28 passed the bill, H. R. 8128, to authorize a permanent annual appropriation for the maintenance and operation of the Gorgas Memorial Laboratory in Panama. The measure calls for \$50,000 to be paid to a benevolent corporation organized to establish and maintain this laboratory for the study of tropical and preventive medicine. The Republic of Panama has already donated the site, and the president of this republic has pledged an appropriation of half a million dollars or more for the construction of the laboratory. By the terms of the bill each of the Latin-American countries is to be invited to contribute, the total not to exceed 75 per cent of that appropriated by the United States. One member of Congress seemed to express the sentiments of the whole House when he said, "I think the passage of this bill is the best thing we can do from the national standpoint, from sanitary and health needs, and from the standpoint of admiration for and as a memorial to one of the world's greatest physicians." Then the House broke into applause.

Other Matters before Congress— A revision of the International Sanitary Convention of 1912 has been ratified by the Senate. The text of this treaty appears in full in the *Congressional Record* for March 22, 1928. In addition to the numerous bills granting federal medical relief to various classes of veterans suffering from tuberculosis, a new one, H. R. 11948, would extend such relief to any person discharged from the Navy or Marine Corps who contracted the disease as a result of duty. A bill for the advancement of funds in connection with the enforcement of acts relating to narcotic drugs passed the Senate on March 22. A \$15,000,000 hospitalization program has been agreed upon

by the Committee on World War Veterans' Legislation of the House and was to be embodied in legislation.

An interesting study of pending legislation relating to federal medical and surgical relief for diseases and injuries of civil life, by Dr. William C. Woodward, appears in the *American Medical Association Bulletin* for February, 1928.

A case of Medical Negligence in Ohio—A physician who treats a patient for smallpox must report the case to the health officer, and it is also his duty to warn other persons, who are known by him to be in dangerous proximity to the patient, of the existence of the disease. Failure to perform this duty will constitute negligence on the part of the physician and a person injured thereby may recover damages. Instructions to this effect must be given by a trial court in its charge to the jury, and a refusal to do so constitutes prejudicial error.

These principles outlining the proper duties of physicians have recently been enunciated by the Supreme Court of Ohio in the case of *Jones v. Stanko*, a copy of which has been sent us by James E. Bauman of the State Department of Health. The facts were that from a Tuesday to the following Saturday, one Dr. Washington L. Jones attended a patient who had black smallpox. This physician did not report the disease to the local health officer, and he permitted Mr. Stanko to wait on the patient, assuring Mr. Stanko that no danger was involved in such service.

Both the patient and Mr. Stanko died of black smallpox, the latter death obviously being due to the incompetence or negligence of the physician. The law requires a man who engages in the general practice of the medical profession to know when he is dealing with diseases which are dangerously contagious, and he must exercise ordinary skill and care relative to these matters.

The trial court refused to charge the

jury as to the negligence of the physician and he won the case there. This decision was properly reversed by the Court of Appeals, whose action was sustained on appeal to the court of last resort in the state, the Ohio Supreme Court. This is a good decision, promoting public health by pointing clearly to the duties of the physician to the people.

Miscellaneous Items—The Chicago drainage cases were set for a hearing on April 23 before the U. S. Supreme Court on exceptions to the report of the special master, Charles Evans Hughes.

A donation to a fund to combat disease is deductible in computing income tax, in the opinion of the General Counsel of the U. S. Bureau of Internal Revenue (Memo. 3016). The opinion, with the method of computation in the particular case is given in the *United States Daily* for March 19, 1928.

A world conference of immigration, including consideration of health, opened at Havana on March 31.

The United States sent an unofficial delegate to attend the opium conference at Geneva beginning April 12.

Provisions in state laws for indemnities for tuberculous cattle is given in the *Congressional Record* for March 28, 1928 (page 5707).

A tack in a dish of strawberries which later lodged in a customer's jaw has been held not to constitute evidence of negligence by a restaurant keeper, according to a recent decision of the U. S. Circuit Court of Appeals for the Third Circuit, Horn & Hardart Baking Co. v. Lieber.

Conviction for the illegal taking of clams from areas proscribed by the State Department of Public Health has been upheld in Massachusetts in Com. v. St. John, 159 N. E. 599.

BOOKS AND REPORTS

The Principles of Ante-Natal and Post-Natal Child Hygiene—By *W. M. Feldman, M. D., M. R. C. P. (Lond.), F. R. S., (Edin.), London: John Bale, Sons & Danielsson, Ltd., 1927. Price 25s. (American Public Health Association, \$7.50.)*

This is a type of book which one reads with delight, but reviews with a great feeling of diffidence. Indeed criticism of such a book can only be regarded as presumption on the part of the majority of reviewers.

It is divided into three parts, the first of which defines the subject, gives a general survey of it, a most interesting chapter on the history and development of child hygiene, statistical methods, antenatal and intranatal mortality and maternal mortality. The second part is devoted to antenatal hygiene, while the third part is given to hygiene from birth through the childhood stage, with a short chapter on "Adolescence or Puberty."

In reading the chapters, one finds no question left unanswered, and though some deal with rather difficult subjects, they are written in such clear language that the understanding of them is easy to any educated person. The only exception to this statement is the one on biometrics which, though clearly put, will be found difficult by many readers. It requires some training in mathematics.

The author well states in his preface that he believes this is the first book of its kind in any language. It is designed to appeal to educated and thoughtful persons, whether lay or professional, who are interested in the welfare of children, and, we might add, the race.

The book gives many quotations from

ancient as well as modern writers. It is abundantly illustrated and contains a large number of portraits of those who have worked for the benefit of children, in the past as well as more recently, in addition to which there are 159 illustrations in the text. Among the illustrations one of particular interest shows the headstones of Benjamin Jesty and his wife, the inscriptions on which are easily legible. Besides the illustrations and photographs, there are many tables and charts.

We feel safe in predicting that for many years this book will hold its own as a standard text and reference. It is written as a companion volume to *The Principles of Ante-natal and Post-natal Child Physiology*, which appeared in 1920, and was favorably received. The printing of the book is excellent, but unlike most English books, the paper used is heavy and does not have a mat surface.

This book deserves a longer and more detailed notice, though it would be impossible to mention the many things worthy of special commendation. It must be read to be appreciated.

M. P. RAVENEL

The Chemistry of Water and Sewage Treatment—By *Arthur M. Buswell. New York: Chemical Catalog Co. 1928. 362 pp. Price, \$7.00.*

While written primarily for chemists, this book is of much interest to the sanitary engineer and the biologist interested in water purification and sewage treatment. The author prefaces the more technical discussions with two introductory chapters dealing with recent developments in chemical theory and with the chemistry of colloids. Although to the

chemist, it may seem almost absurd to discuss the subject of colloids in 20 pages, such a condensed and well written presentation is a boon to the bacteriologist.

The chemistry of water treatment is discussed in chapters dealing with water softening, filtration and disinfection. One chapter is devoted to the chemistry of coagulation and is particularly to be commended. No attempt is made to give detailed descriptions of filters or to describe operating practice.

The chapters on sewage are of interest because the author has attempted to collect and digest our knowledge on the biology of the methods. The statement, "comparatively little biological data of practical value are available" cannot be too strongly emphasized. There has been a tendency to regard the changes which take place in the trickling filter and in the activated sludge process as purely physico-chemical in character. We are glad to find that the author does not sympathize with this point of view, but apparently believes that colloidal reactions and bio-chemical changes induced by microorganisms are at least equally important.

The book is a real contribution to what we hope some day to be able to call "the science" of water and sewage treatment.

JOHN F. NORTON

Pulmonary Tuberculosis—By David C. Muthu, M.D. (2d. ed.) New York: William Wood, 1927. 381 pp. Price, \$5.00.

In this second edition of his book, Dr. Muthu has added an introduction of some 120 pages to his old text. In fact, there is very little change in the old text and the only new thing about the book is the introduction.

In it the author takes up discussion of the tuberculosis problem from the statistical, research, clinical and environmental points of view, with some extraneous observations at the end on

tuberculosis in India. As a summary of existing knowledge of tuberculosis work, the book has some merit and would have more if it were not for the fact that the author seems to have gone on the fallacious theory that everything appearing in print is authentic. For example, Abrams of late lamented quack fame, with his electronic theory which has been so completely discredited in this country, has been quoted with such authorities as Koch, Webb, Calmette and other workers of genuine responsibility and fame. Even more, the author goes out of his way to give a somewhat fulsome laudation to the Abram's theory, which is enough to discredit the book entirely.

PHILIP P. JACOBS

The Concise Oxford Dictionary of Current English—Adapted by H. W. Fowler and F. G. Fowler. Oxford University Press, 1926. 1064 pp. Buckram, Price \$3.50.

To everyone interested in the correct use of words, this dictionary will be a joy. The names of the two men who have adapted it from the *Oxford English Dictionary* are sufficient guarantee of its value, and those who have used *A Dictionary of Modern English Usage*, by one of the authors of this book, will be especially glad to have the present volume.

While holding to many of the usages which we Americans recognize as typically English, the authors have given way to a certain extent, though they have "stopped short of recognizing forms that at present strike every reader as Americanisms."

The book is well printed, though some typographical errors have been found. It may be had in a number of bindings, on various papers, and indexed, the prices running as high as \$17.50 per copy. It can be unreservedly recommended to everyone, and especially to those who attempt to write.

M. P. RAVENEL

A Treatise on Hygiene and Public Health—With Special Reference to the Tropics—By Birendra Nath Ghosh, F.R.F.P. & S. (Glasg.) Revised and largely rewritten with the advice and assistance of Colonel A. B. Fry, M.D., (Lond.), D.P.H., (6th ed. rev.) Calcutta: Scientific Publishing Co., 1927. Price, 10 s.

When an author is called upon for six editions in a period of 15 years, he is entitled to believe that his work has been successful. The first four editions of this book were written in connection with J. L. Das. The last two have been published under the present author's name.

The text considers the usual subjects commonly discussed under the head of hygiene and public health, but this book is particularly interesting as giving us conditions as seen in India. There were certain defects in the fifth edition which have been largely remedied in the sixth. We believe, however, that too little is said about dried milk, for example, to which only a few lines are devoted.

The author advocates cremation, which is needed in India probably more than any other country in the world. When we remember the overcrowding and the beliefs which have become ingrained through many generations, we can appreciate the difficulties which the hygienist faces in that country. Infant and maternal mortality are still terrifying, and it is estimated that from 60,000 to 75,000 women die every year from conditions connected with child bearing.

Vitamins are included in this edition, though there is some confusion about the name. Funk believed that they were amines, and only later has the "e" been dropped from the name as given by their discoverer.

The volume bears throughout the stamp of careful study, honest interpretation of the facts, and common sense. The English is exceptionally good, in spite of the fact that it is not the native

language of the author. A glossary giving the English equivalents of the Indian names used would improve the book, though most are found somewhere in the text. The illustrations and printing are good. The book doubtless does an enormous amount of good in the country for which it is written, and can be read by all hygienists with pleasure as well as profit. M. P. RAVENEL

Cultivating the Child's Appetite—By Charles Anderson Aldrich, M.D. Macmillan, 1927. 127 pp. Price, \$1.60.

Dr. Aldrich's book covers a very important subject in a most unusual way. It is simple, straightforward and to the point. I believe every mother would profit greatly by reading it and the children should profit even more.

There are a few important points to which I take some exception:

More stress should be laid on the fact that anorexia is due to the shortcomings of the parents rather than to the children. Of course, there may be a few exceptions and these are due to outside influence such as teachers or nurses. This is very well illustrated by the fact that poor children are seldom afflicted while the children of the rich are very commonly affected in this way.

More stress should be laid on causes for this condition. I believe the cause of poor appetite is very largely physical. It is the result of disease or at least an abnormal condition of the patient. Any child with a poor appetite should be considered sick. The causes of this condition are too much excitement, too much discipline, too much work. More is expected of the rich child than of the average child and in consequence the former falls under the load he is forced to carry. He may appear all right but in reality is not well. Instinct tells him not to eat and if left to himself long enough he will correct the condition. When a child does not want to eat it should not be forced. ROBERT E. HUMPHRIES

An Experiment With Time—
By J. W. Dunne. New York: Macmillan,
 1927. 208 pp. Price, \$2.50.

The only way to find out whether the author is dealing with real experience or with a hoax in the grand style is to try to repeat his "experiments." These experiments consist of recording as fully as possible details of what is in one's mind at the moment of waking or when in a semi-dormant condition, and subsequently comparing these items with waking experience. In a large number of cases the experimenter will discover these dreams have anticipated events. What that proportion is can never be ascertained of course, since we notice only what we notice, and we shall not notice the dreams which are never recalled in subsequent waking experience; nor should we count the dream items that have to do with commonplace events and experiences that occur before as well as after the time of our record. Mr. Dunne speculates learnedly on the nature of space and time, and leaves us with the impression that perhaps our time experience is after all reversible. While he has a number of very striking examples of dream stuff apparently anticipating experience, it must be said that most of his stories represent no more than the fact that a minute fragment of the situation is capable of recalling a totally different situation in which a few elements are present in common. Until we have a large body of similar "observations" against which it is possible to check, we shall not be convinced that Mr. Dunne has really discovered a novel quality in the structure of time.

The book on a whole is an introduction to a new interpretation of the universe which the author calls serialism, with distinct psychological, theological, and teleological aspects. It is proverbially difficult for a new philosophy to gain recognition; and the reviewer would really like to help.

B. C. GRUENBERG

The Bacteriolytic Tank System in South Australia—
By W. Ramsay Smith, M.D., D.Sc., F.R.S. (Edin.) (7th ed.) Adelaide: Gov. Printer, 1927, 48 pp.

This pamphlet contains very little new information. Its scope "is limited to the problems of sanitation in unsewered areas, the sanitary appliances that are obtainable and the sanitary standards that are attainable in such areas."

To those interested in the background of the septic (bacteriolytic) tank in Australia and the literature thereon, portions of the pamphlet will be valuable.

The description of the tank is sufficient to permit an understanding of it, but from the viewpoint of practice in this country the sketches and plans included in the pamphlet could not be considered as particularly useful in helping the rural house owner to build his own tank. In parallel pamphlets published here, much space usually is devoted to the careful and detailed explanation of form-building; the lumber needed therefor; concrete mixing and such related matters. Explanations of this variety are lacking in this pamphlet.

The last four chapters are devoted to discussing a number of Australian installations; what goes on in the tank; the control of the use of such tanks by the official health agencies of Australia; and the economic value of the tank system to that country. ARTHUR P. MILLER

The Human Body in Pictures—
By Jacob Sarnoff, M. D. Brooklyn, N. Y.: Physicians and Surgeons Book Co., 1927. 120 pp. Price \$2.00.

This is a unique presentation of a visual text of anatomy, physiology and embryology. It is written in a simple compact style. With its wealth of illustration it should appeal to high school students, especially if correlated with their other science work. This book appears to be one of a series on the human body presented by film slides, motion pictures and textbook. B.C.G.

Diseases of the Skin—By Henry H. Hazen, A. M., M. D., (3rd ed.) 248 ill. St. Louis: Mosby, 1927. Price, \$10.00.

A book which has reached the third edition has already run the gauntlet of professional criticism, and if it has met with success, which is usually proved by the demand for new editions, it needs little comment. A striking feature of the present edition is the omission of the usual long discussions on eczema, though the name is still retained in one case, and as a synonym in two others, in spite of the fact that the author states in his preface that the word has been omitted. The wisdom of this is shown by quotations from two other dermatologists:

Eczema is a term commonly applied to any wet or scaly inflammation of the skin, of the cause or nature of which the observer is ignorant.

. . . Eczema is only a sort of dermatological scrap heap out of which from time to time, certain diseases that present a characteristic and definite symptomatology are extracted.

The various skin manifestations of anaphylaxis are given more attention than usual. We commend the author also for omitting the bibliography which, as he says, has been found to be of no value to students.

The book is beautifully printed, has very few errors, and is abundantly illustrated with excellent photographs, most of which are original with the author. We wish our American publishers would use the light paper now available. Although this book contains only 572 pages, its weight is burdensome.

M. P. RAVENEL

Health Problems in Organized Society—*Studies in the Social Aspects of Public Health*—By Sir Arthur Newsholme, K.C.B., M.D. London: P. S. King & Son, Ltd., Orchard House, Westminster, 1927. 253 pp. Price, \$3.50.

The chapters contained in this volume are made up of lectures and addresses given over a period of several years in America and in England. A book of this character is not easy to review, since so

many different matters are treated. There is some repetition, which the author has lessened to a great extent by cross references. Each chapter, however, considers the social aspect of the particular problem under discussion, and stress is laid on the importance of cultivating the sense of personal as well as communal responsibility, and the ethical side of public health work. The author feels that it is more important to secure for each child the fullest mental and moral development possible, than to extend research into diseases, the causes of which are still unknown, though he does not belittle the importance of research.

There are 19 chapters, each of which is well worth reading. The author has been a teacher and public health administrator for 45 years. He has read widely, and frequently gives striking quotations from older writers, whose works are unknown to the majority of the present generation. Throughout the book, he lays especial stress on the moral side of preventive medicine, holding that the health officer who concerns himself only with measures for preventing infection is bound to find his efforts sterile. Alcoholism, tuberculosis and venereal disease have been chosen as the three great subjects with which to illustrate the possibilities of life saving and national health improvement.

There are several chapters on the history of the control of alcohol, besides frequent references to it, the author being strongly in favor of prohibition. While interesting, we believe that he has accepted evidence which is far from having been proved, and some of which has been disproved.

The last two chapters are devoted to the problem of population, in which he confesses that he shows his personal bias in regard to disputed matters. Here again, we think that he has overlooked some facts. He says that the forecasts made by Malthus have proved to be false

up to the present time, though he acknowledges that the population of the world has more than doubled in the last hundred years. He discusses various factors which have interfered with what Malthus predicted, pointing out the changed trend of population seen in Western European countries and America, and believes that it is due to widespread use of contraceptive measures.

The book as a whole shows the distinguished author at his best. Few living men have been so closely in touch with the growth of public health, especially in England, but also in other countries, and none have used their opportunities to better advantage.

Perhaps the most striking feature of the book is the high moral standards which are inculcated, on which everything else seems to depend. He believes strongly in education, holding that the best educator is the man who waits on and aids the development of the human mind, and that our "basic need is to train the behavior of the individual in the varying circumstances of life," the lack of such training being responsible for the continuance of a vast amount of preventable disease.

The printing and make-up of the book are exceptionally good. The paper used is of the light weight so generally found in English books, and so often not found in those of American origin.

M. P. RAVENEL

To Whom It May Concern: A Popular Address About Smallpox and Vaccination—*By William Wanklyn. London: The Voluntary Service Fund. 1927. Price 1/6.*

The Case Against Vaccination—*By Councillor W. Asbury. London: Journal of the Royal Sanitary Institute. Vol. XLVIII, No. 4, 1927.*

From deep convictions growing out of many years of field experience with smallpox, both as physician and as special consultant for the London and other

county councils, Dr. Wanklyn writes with remarkable restraint, and earnestly appeals to his fellow citizens to join in a united effort "to clear smallpox right out of the country once and for all," by means of systematic use of vaccination. There are many dramatic personal episodes, as well as some useful statistical and historical material.

Equally earnest is Councillor Asbury of Sheffield City Council, in his opposition to vaccination. Like so many lay partisans he rests his case primarily on the older fears and suspicions. After all, it is not obvious how so "unnatural" and bizarre a procedure as vaccination can bring about immunity to smallpox. Moreover, fashions and claims have undergone many changes, and there have been deaths and disasters closely associated with vaccination which the writer is unable to reconcile with the vaccinator's present position. Fragmentary quotations from authorities and from statistical records can of course be offset by other quotations; he uses only one set.

The councillor is worried, and it is manifestly insufficient for those who favor vaccination to shout louder.

B. C. GRUENBERG

Boiler Feed Water Purification—*By S. T. Powell. New York: McGraw-Hill. 1927. 363 pp. Price, \$4.00.*

The purification of water for industrial purposes is largely a problem for the factory although several cities in this country have municipal softening plants in operation. Water softening is also practiced in homes located in hard water regions. The discussions in this book deal with all phases of the problems involved, such as chemical coagulation, filtration, various methods of softening, distillation, the use of boiler compounds, prevention of foaming and priming and of corrosion and the use of feed water heaters. Methods for the analysis of boiler waters are given in detail.

JOHN F. NORTON

HEALTH DEPARTMENT AND OTHER REPORTS

IRA V. HISCOCK

Providence, R. I.—A valuable set of public health, milk inspection, and vital statistics reports for the year 1926 has been received from Providence. These reports conform in attractive appearance, good printing and subject content to the high standard established in this city many years ago. They are worthy of study by health administrators.

The report of the superintendent of health gives a birth rate of 22.5, a death rate of 13.1, and a marriage rate of 15.9 for the year. A classified financial statement for this city of 270,400 population shows that \$192,937 were expended by the health department, but of this amount, \$93,259 were expended for garbage removal. One of the interesting features of the report is a section on the appraisal of health work in Providence according to functions.

In a section dealing with the supervision of infants and preschool children, it is interesting to note that the distribution of prenatal letters to prospective mothers was begun in October, 1925. From that time to the end of 1926, 1,379 requests were received for these prenatal letters. Five nurses supervise the babies delivered by midwives, up to 2 years of age; one nurse supervises the infants and young children in licensed boarding homes and the infants of such unmarried mothers as are not under the supervision of private agencies; one nurse makes one visit upon each infant delivered by a physician, provided the mother is not on the maternity service of the District Nursing Association, or delivered at the Lying-in Hospital. Thirteen child welfare stations were carried on by the Providence Child Welfare committee, the examining doctors being engaged and paid by the health department. The district nurse association employs 17 nurses on its children's

services and during the year they had 5,993 infants and preschool children (68 per cent under 1 year) under supervision. The nurses made 38,452 home visits to these children in addition to 3,999 prenatal visits to 1,403 prospective mothers. A total of 10,308 visits were made by infants and young children to the welfare stations. In a newly opened preschool clinic, children not only are given a complete physical examination, but generally receive toxin-antitoxin treatment for diphtheria immunization. An infant mortality rate of 68 is recorded.

Of the 20,646 school children examined, 59 per cent were found to have defects. Treatment of defects was secured in 70 per cent of the instances recommended. Among the special classes and clinics there is a psychiatric clinic where 483 examinations were made. Several of the problem cases were fully studied at the Problem Clinic of the Rhode Island Hospital and at the Mental Health Center at the Esek Hopkins School. There are 11 open air schools, 2 for pupils of grammar grades and 9 for primary grade children. A school for crippled children was opened in 1925, where a physician examines all applicants upon admission and before leaving.

The superintendent of health is also ex-officio inspector of milk. According to regulations effective January 1, 1926, it was provided that all milk sold in Providence should be certified or from cows under government supervision, or pasteurized. Milk from cows under government supervision must not have more than 100,000 bacteria per c.c., and pasteurized milk must not have over 1,500,000 before pasteurization, and not over 100,000 after pasteurization. A law enacted at the instigation of the farming interests has fixed the maximum

bacterial content of Grade A pasteurized milk as 25,000. The average bacterial count of the Grade A pasteurized milk sold under the state law after July 1 was 12,000.

The vital statistics report contains important tables frequently used. Deaths are classified by months, according to sex, marital condition, color, nativity and parentage; by month and cause; and by sex, age and cause (International List). Births are classified according to season, sex and color; and according to number of child and age of mother. Of the 6,090 births, 2,576 occurred in hospitals. A general summary table, condensed into 5-year periods, gives important statistical data since 1855. Deaths under one year are classified by cause and age, as well as according to nativity of mothers.

Queensland—The annual report of the Commissioner of Public Health for the year ending June 30, 1927, opens with brief statistical records of the birth, death and infant mortality rates for that state and also for other states of the Commonwealth and several parts of the Empire. Infant mortality rates in 1926 are noted as varying from 39.8 in New Zealand and 50.4 in Queensland, to 57.6 in New South Wales. Diphtheria apparently reached its peak during the year, although not confined to a particular area.

Arising out of a deputation representing the Australian Coachmakers Employees' Federation and the House Painters' Union, which waited upon the Minister with reference to the use of the spray "gun" in the application of paints and the toxicity of the substances employed in such processes, samples of all "spray paints" in use upon the local market were procured and have been analyzed by the government analyst. As a result of the discovery that soda and water issued from certain soda fountains contained lead in , excessive

amounts, a series of samples were obtained from all cafes and refreshment rooms. This necessitated the dismantling and overhauling of a large number of fountains when it was found that the interiors of certain carbonators were jointed at the seams, at the ends of agitator shafts, and elsewhere with solder which contained lead. All faulty solder was replaced with lead-free material, and in numerous instances fresh tin lining was provided.

Madras—Features of the health officer's 1926 report which first impress the reader are the size of page (8¼"x 13"), the large size of type and the soft paper. Paper of glossy finish is used here only when photographs or statistical charts are included. The report occupies 209 pages. High mortality and morbidity rates are explained to a considerable extent on the basis of economic problems. Considerable laboratory work has been carried on in the control of water supplies. Housing inspection has been active and attention is directed to the need of a comprehensive development plan of housing for the entire city, based on a scientific as well as a business viewpoint. The National Health and Baby Week celebrations were conducted in the South Indian Athletic Association grounds and premises from the 14th to the 20th of January. Charts, posters, health models, and leaflets were widely utilized. Excellent photographs of the child welfare motor car and of maternity and infant clinics add interest to the report.

Education of Employed Youth—The proceedings of a special conference held in New York* on the education of employed youth are worthy of study by educators and health workers. A carefully prepared article on health education in the continuation schools presents data

* The University of the State of New York, Albany, 1927.

which suggest among other things the shortcomings of School medical and nursing programs as at present carried out. "We had either failed completely to recognize persistent defects or had failed to persuade the families of boys of the desirability of improving or correcting the various types of physical defects discovered."

It is stated that before planning any system of health instruction in continuation schools, the type of audience and the background must be considered. Youth in industry must be cautioned effectively against the kind of hazards they are facing and where there are continuation schools in communities, where certain types of industries are likely to absorb children, special attention should be paid to train the children in the avoidance of the hazards in the particular industries. "There can not be any really effective education of the children in continuation schools until they have a point of departure for their education, and by that I mean a thorough medical examination." It is emphasized that there is no greater damage to health, to resistance to disease, than allowing children of school age to have insufficient sleep and rest. Special precautions in this regard are necessary for children who have the combined burden of earning a living and at the same time keeping on in school education. An outline of a "practical health program for employed children" is contained in this report for the guidance of those concerned with the organization of the health and recreation work in the continuation schools.

Hamilton, O.—A journey through the city health district of Hamilton, during the last 3 months of 1927, is made possible for readers of the sanitary report by means of many cartoons, with brief tabular material and discussion. The form of presentation is sufficiently unique to cause the average reader to

peruse the entire report. Information is given regarding the scores of barber shops, dairies, restaurants, confectionery and grocery stores, ice cream plants, markets, and drug stores. The periodic health examination by the family physician is featured.

Scott County, Ky.—The population of Scott County is indicated in the 1927 annual report of the Health Unit as follows: white 13,800, colored 1,518. This county covers an area of 290 square miles, there being 2,753 homes and a school enrollment of 2,800. The director of the health department emphasizes the value of the coöperation received from the medical profession, educational institutions, the press and civic clubs. Laboratory services have been rendered by the State Board of Health and experiment stations. Physical examinations have been made of children in the rural and city schools and the college, defects have been noted and efforts have been made by the follow up work of the nurses to secure their correction. Commendable progress has been made in health education by means of lectures, bulletins and nursing follow up work.

The Rotary Club has coöperated in educational work and has offered as a stimulus for better conditions in rural schools two attractive prizes. These prizes are awarded to the schools attaining the highest point of efficiency, as governed by the following requirements: vaccination, heating, ventilation, foundation, lighting, seats, water supply, water service, toilets, playground and attendance. During the 5-year period preceding the full time health department, there was an average of 218 deaths in the county as compared with an average of 189 annual deaths during the 5-year period of the full time department. Particularly noteworthy has been the reduction of deaths of infants under one year of age.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Health Education—A British view of the need for, the principles of, and the available avenues for educating the public in health. A well presented statement avoiding mechanical details.

BEATTIE, N. R. Public Education in Health. Med. Off., 39:8 (Feb. 25), 1928.

Respiratory Diseases in Industry—Of the absences of one or more days from the Edison Company of Boston, 54 per cent were caused by respiratory diseases. And of this number, 71 per cent were common colds. The monthly incidence of respiratory diseases is shown.

BRUNDAGE, D. K. Importance of Respiratory Diseases as a Cause of Disability Among Industrial Workers. Pub. Health Rep., 43:11 (Mar. 16), 1928.

Tonsillectomy and Respiratory Infections—Students of the University of Michigan who had had their tonsils removed had 40 per cent more acute respiratory infections than those who had not been favored with the surgeon's knife. The author concludes significantly: "The need for conservation in tonsillectomy was recently voiced by Canfield."

FORSYTHE, W. E. The Health Record of University Students as Related to Tonsillectomy. Pub. Health Rep., 43:10 (Mar. 9), 1928.

Physical and Mental Relationships—The nervous system tends to grow in obedience to inborn determiners and is very little influenced by malnutrition, pubescence, etc.

GESEL, A. Precocious Pubescence and Mental Growth. J. A. M. A., 90:11 (Mar. 17), 1928.

Malta Fever—The recommendation of the author is that all laboratories should perform agglutination tests for *B. melitensis* on all specimens submitted

for Widal test. In Iowa malta fever presents a health hazard comparable to that of typhoid.

HARDY, A. V. Malta Fever: A Problem for State and Municipal Laboratories. Pub. Health Rep., 43:9 (Mar. 2), 1928.

Differential Diagnosis—Smallpox, Chicken Pox—A useful summary of the points of differential diagnosis between smallpox and chicken pox, including distribution, appearance, development of lesions, and the history of the case.

LAIDLAW, F. W. Smallpox and Chicken pox—the Differential Diagnosis. New York State J. Med., 28:6 (Mar. 15), 1928.

Educating to Keep Fit—Health officials will be edified but not gratified to find the estimation of the value placed upon their services by this broad-visioned physician in his discussion of the need for educating people to keep fit. The author looks to Hollywood for a deliverer.

McKENNIE, L. H. The Business of Getting Well. J. A. M. A., 90:11 (Mar. 17), 1928.

Trachoma Prevention in the South—The extent of the infection throughout the southeast and southwest is summarized. Trachoma preventive measures act as an important influence in inaugurating full-time rural health administration.

MOSSMAN, P. D. Trachoma in the State's Health Program. Pub. Health Rep., 43:8 (Feb. 24), 1928.

Infant Mortality—There was a 29 per cent decrease in infant mortality during the decade 1915-1924 in the registration area. The greatest improvement occurred among colored infants in rural areas for whom the least is done under our various infant welfare schemes. During the same decade there

was an 8 per cent increase in maternal mortality.

STERLING, E. B. Infant and Maternal Mortality in the United States. Pub. Health Rep., 43:9 (Mar. 2), 1928.

Aerobic Flora of Colds—Green streptococci were found in all throats and Gram-negative cocci in most; frequently the influenza bacillus, pneumococcus, and diphtheroids were found. During "colds" foreign organisms appeared in some throats; in others the same organisms became dominant.

NOBLE, W. C., et al. Studies of Acute Respiratory Infections. J. Prev. Med., 2:2 (Mar.), 1928.

Venereal Disease Prevalence—In 14 urban and rural communities, surveys were made to determine the number of persons under treatment or observation at a given time. A rate of 11.6 per 1,000 population was reported; 4.96 for gonorrhea, and 6.65 for syphilis.

PARRAN, T., JR. Venereal Disease Prevalence in Fourteen Communities. Ven. Dis. Inform., 9:2 (Feb. 20), 1928.

Tuberculosis Trends—Although tuberculosis mortality has been halved in Chicago during the present century, it has increased since 1922, due probably to the increase in the negro population. Under 11 years the rate in negroes is from ten to twenty times that of white children.

ROBEY, L., and FALK, I. S. A Statistical Study of the Mortality from Tuberculosis in the City of Chicago. J. Prev. Med., 2:2 (Mar.), 1928.

Physical Examinations for School Children—A consideration of the value of breath-holding and blood pressure tests in the examination of school boys.

SIMPSON, J. V. A. The Assessment of Physical Fitness. Med. Off., 39:9 (Mar. 3), 1928.

Venereal Disease Control Measures—Universal medical treatment that is adequate; follow-up that makes it effective; extended research; true ethi-

cal guidance, are some of the author's projects intended to bring venereal diseases demonstrably nearer control in America as they have been in Europe.

STOKES, J. H. Venereal Disease Control. J. A. M. A., 90:10 (Mar. 10), 1928.

Benzol Poisoning in Women—One of every three women exposed developed symptoms of benzol poisoning; young being more susceptible than old workers.

SMITH, A. R. Chronic Benzol Poisoning Among Women Industrial Workers: A Study of the Women Exposed to Benzol Fumes in Six Factories. J. Indust. Hyg., 10:3 (Mar.), 1928.

Early Diagnosis of Measles—In this discussion is included a description of the "measles line," a congestion across each lower lid at the margin of the tarsal cartilage, following the onset of fever.

STEMSON, P. M. The Earlier Diagnosis of Measles. J. A. M. A., 90:9 (Mar. 3), 1928.

Immunizing Against Pneumococci—Immunity was produced in rabbits by the injection of killed cultures or autolysate of pneumococci either into the buccal mucosa or other usual routes. The site to which the test dose of live pneumococci was applied had no effect.

STUPPY, G. W., and FALK, I. S. The Immunization of Rabbits Against Experimental Pneumococcus Infections. J. Prev. Med., 2:2 (Mar.), 1928.

Broad Tapeworm of Man Reported—The plerocercoid stage of the broad tapeworm of man has been demonstrated in several varieties of fish found in Lake Superior. The source presumably is the colonies of Scandinavian immigrants of that region.

VERGEER, T. *Diphyllbothrium latum*, the Broad Tapeworm of Man. J. A. M. A., 90:9 (Mar. 3), 1928.

Sterilizing Milk Bottles—The more general use of individual milk bottles as serving containers leads to the question

of adequate chemical sterilization. Calcium hypochlorite solution even at 500 parts per million cannot be depended upon to kill human tubercle bacilli, but available chlorine of a strength of 95 parts per million will kill in three minutes.

WADE, E. M., et al. Chemical Sterilization of Milk Bottles in Relation to Tubercle Bacilli. *J. Bact.*, 15:3 (Mar.), 1928.

Diphtheria Bacillus Toxin Production—Diphtheria bacilli, having lost their toxin-producing characteristics when grown on certain synthetic culture media, failed to recover the characteristic when restored to ordinary media or when inoculated into animals. A synthetic, protein free medium is suggested which permits cultivation and toxin production.

WADSWORTH, A., and WHEELER, M. W. The

Attenuation and Toxin Production of the Diphtheria Bacillus. *J. Infect. Dis.*, 42:2 (Mar.), 1928.

Milk-Borne Paratyphoid Fever—an outbreak of paratyphoid B fever causing 140 cases in England is reported. A woman on the offending dairy was found to be a carrier. The number of carriers resulting from the epidemic suggest to the author the need for a general immunization of the exposed population.

WARD, I. V. I. An Outbreak of Paratyphoid B Fever. *Lancet*, 1:8 (Feb. 25), 1928.

Epidemiology of Pneumonia—A study of the incidence of pneumonia in relation to temperature, climate, and industrial conditions in Great Britain. Not particularly revealing.

WOODS, H. M. On the Statistical Epidemiology of Respiratory Diseases. *Lancet*, 1:9 (Mar. 17), 1928.

SCHOOL POSTURE AND SEATING. By Henry Eastman Bennett. New York: Ginn, 1928. 323 pp. Price, \$2.00.

HEALTH RECORD FOR WOMEN. By J. Theron Hunter. Baltimore: Williams & Wilkins, 1928. 64 pp. Price, \$1.00.

THE PENNSYLVANIA ASSOCIATION OF DAIRY AND MILK INSPECTORS. Fourth Annual Report. Compiled by George C. Morris, Secretary-Treasurer. Harrisburg, Pa., 1928. 260 pp. Price, \$1.00.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

UNIVERSITIES and technical schools throughout the country are offering courses in public health and preventive medicine during their summer sessions. The following does not pretend to be a complete list of schools giving such courses this summer, but it represents the schools that replied to the circularization made by the *American Journal of Public Health* and *The Nation's Health* for the benefit of those readers who contemplate pursuing study in public health this summer.

UNIVERSITY OF CHICAGO, Chicago, Ill.

June 18-July 25 (First term)

July 25-August 31 (Second term)

Hygiene and Bacteriology

Public Hygiene. This will deal with problems of community hygiene such as water supply, sewage disposal, food supply, infant welfare, tuberculosis, insect-borne infections.

Immunity in Relation to Preventive Medicine

Public Health Problems

Sanitary Surveys

Public Health Nursing. Supervision in Public Health Nursing.

School Hygiene

Physical Education

COLUMBIA UNIVERSITY, DeLamar Institute of Public Health, College of Physicians and Surgeons, New York, N. Y. July 9-August 17.

School Health Inspection

Administration of Health Work in Schools

Organization and Supervision of Health Education

Teaching of Health in Secondary Schools and Colleges

Health Care of Children

Research in Child Health

Physical Education

Nutrition in Health Education

Mental Hygiene

Public Health Nursing

School Nursing

Nursing Supervision in Clinics and Out-Patient Departments

Sanitary Science

Industrial Medicine

Public Health Administration

Bacteriology

Public Health Engineering

CORNELL UNIVERSITY, Ithaca, N. Y. Opening July 3.

Physical Education. Course in the organization, administration and methods of teaching physical education.

Measurements of School Children. This course will stress the practical application to problems of growth and development.

Hygiene of the School Child and Adolescent

Health Inspection of School Children

This course is planned to familiarize teachers with facts and methods necessary for making an effective health inspection of school children.

HARVARD UNIVERSITY, Cambridge, Mass. July 2-August 11.

Principles and Problems of Hygiene.

This will emphasize disease prevention and also the interpretation and organization of material in hygiene for instruction and application.

Physical Education

MASSACHUSETTS INSTITUTE OF TECHNOLOGY, Cambridge, Mass. July 2-August 14

Methods of Teaching General Biology
Bacteriology

Health Education Methods

Hygiene of School Child

Public Health Laboratory Methods

Public Health Institutes for Health

Officers and Public Health Workers

MICHIGAN STATE COLLEGE, East Lansing, Mich. June 18-July 27.

Medical Biology. This course is designed for persons trained in hospital and public health laboratory procedure.

Bacteriology

Hygiene

UNIVERSITY OF MICHIGAN, Ann Arbor, Mich. June 25-August 17

General Hygiene and Public Health
School Hygiene

Methods and Materials in Health Education

Public Health Nursing, Principles and Administration

Public Health Institutes will be held each Friday and Saturday throughout the six weeks of the summer session for intensified study in public health work.

UNIVERSITY OF MISSOURI, Columbia, Mo. June 7-August 3

Physical Education

Nursing

UNIVERSITY OF NEW MEXICO, Albuquerque, N. M.

The Elements of School Health. This course of 16 lectures will be given by members of the staff of the New Mexico Bureau of Public Health.

NEW YORK UNIVERSITY, New York, N. Y. July 9-August 17.

Education in Health. This course is designed for superintendents, principals, teachers, and others responsible for health instruction and supervision in schools.

Health of School Children

NORTHWESTERN UNIVERSITY, Evanston, Ill.

Physical Education and Hygiene for Public Schools

OREGON STATE AGRICULTURAL SCHOOL, Corvallis, Ore. June 18-July 27.

Methods of Health Education

Problems in Nutrition

Child Care Nursing

Physical Education

Home Economics

PENNSYLVANIA SCHOOL OF SOCIAL AND HEALTH WORK, Philadelphia, Pa.

Public Health Nursing

Public Hygiene and Sanitation. These courses will be given under the direction of the Department of Public Health Nursing.

UNIVERSITY OF PENNSYLVANIA, Philadelphia, Pa. July 2-August 11

Hygiene and Physical Education

UNIVERSITY OF ROCHESTER, Rochester, N. Y. June 27-August 3

Mental Hygiene of Childhood and Adolescence

Methods in Health Education. This course also includes devices for the development of child health habits and is designed for classroom teachers, physical education directors and school nurses.

STANFORD UNIVERSITY, Palo Alto, Calif. June 21-September 1.

Public Health Nursing

Health Department Administration.

This will consist of lectures on the activities, organization and powers of public health departments, supplemented by laboratory work and work in the field.

Physical Education and Hygiene

UNIVERSITY OF WASHINGTON, Seattle Wash.

June 12-July 17 (First term)

July 18-August 22 (Second term)

Principles of Physical Education.

Physical Education Administration.

Nutrition

Bacteriology

Principles of Public Health Nursing and Administration

The Health Education Movement.

This course is planned for school administrators and classroom teachers

in elementary and secondary schools and for school nurses.

WESTERN RESERVE UNIVERSITY, School of Applied Social Sciences, Cleveland, O. June 18-July 27.

Principles and Practices of Public Health Nursing
Health Education
Psychiatry

UNIVERSITY OF WEST VIRGINIA, Morgantown, W. Va.

Hygiene and Sanitation

UNIVERSITY OF WISCONSIN, Madison, Wis.

June 25-August 3.

School Hygiene and Health Teaching.

This course is arranged especially for principals, superintendents and directors of health education.

Supervision and Organization of Health Education. This course is for those who will give courses in health education, in their own teaching institutions.

Bacteriology (As related to sanitary problems)

Public Health. Lectures and field work for medical students.

CALIFORNIA PUBLIC HEALTH NURSES INSTITUTE

THE annual Institute for Public Health Nurses will be held under the joint auspices of the Summer Session of the University of California and the State Department of Public Health, at Berkeley and Los Angeles. The Berkeley institute will be held July 9 to 20; and the institute at Los Angeles will be held July 23 to August 3, inclusive.

CLINICAL THERMOMETERS

THERE was a conference of manufacturers, distributors and organized users of clinical thermometers on March 30, at the Department of Commerce in Washington, D. C. At this conference a standard for the minimum requirements in manufacturing clinical thermometers was adopted, which will be effective on October 1, 1928, and which allows one year—until March 30, 1929, for the clearance of existing stocks. These standards will be revised annually.

PUBLIC PLAYGROUNDS

THE Harmon Foundation has granted \$40,000 for the development during 1928, of permanent public playgrounds in new residential developments. The awards will be directed by the Play-

ground and Recreation Association of America, New York, N. Y.

SAFETY EDUCATION

A graduate fellowship of \$1,000 at Teachers' College, Columbia University, for the year 1928-1929 is offered by the National Bureau of Casualty and Surety Underwriters for work on constructing a course of study in Safety Education for Secondary Schools.

ARIZONA HEALTH CONFERENCE

A PUBLIC Health and Sanitary Conference at the University of Arizona, Tucson, arranged by the State Board of Health, was held April 17 and 18. The program included milk inspection and analysis, public water supplies, municipal and rural sewage and garbage disposal, and other public health topics.

BEST BOOK FOR PARENTS

DOUGLAS A. Thom, M.D., Director, Division of Mental Hygiene, Massachusetts Department of Mental Diseases, has been awarded the medal for the best book for parents published during 1927. The medal, which is presented by *Children, The Magazine for Parents*, was awarded for Dr. Thom's book, *Everyday Problems of the Everyday Child*.

THE LABORATORY

A new publication is issued by the Technical Service Department of the Fisher Scientific Co., Pittsburgh, Pa. *The Laboratory* is issued for "those interested in keeping informed on the latest developments of laboratory apparatus and technic." The initial issue carries a description of several new laboratory apparatuses, recently put on the market.

TUBERCULOSIS ERADICATION IN CATTLE

A tabulated summary just issued by the Bureau of Animal Industry, U. S. Department of Agriculture, shows the progress of tuberculosis eradication work in coöperation with the various states. Nearly three-fourths of the number of cattle are in herds which have successfully passed one or more tuberculin tests.

More than 2 million cattle are accredited as free from tuberculosis, as the result of a series of tests. As the result of systematic testing, bovine tuberculosis in the United States is gradually being reduced.

MEDICAL PROGRESS

THE American Association for Medical Progress has published the first issue of a new publication, which will be issued quarterly. This is *Medical Progress*. Benjamin C. Gruenberg, is Editor, and articles have been contributed by Dr. Gladys H. Dick of the John McCormick Institute for Infectious Diseases; James E. Peabody of the United States Congress. Dr. Gruenberg has contributed notes on the commemoration of the four great scientists, whose centenaries are being celebrated this year—Von Baer, Hunter, Harvey and Malpighi. News notes and items of interest are included, which will interest laboratory workers and health officers throughout the country.

ANOTHER SACRIFICE TO SCIENCE

THE most recent worker to lose his life from Rocky Mountain spotted fever is A. Leroy Kerlee, who was employed in the U. S. Public Health Service laboratory at Hamilton, Mont., as a bacteriologist. This disease has caused the death of 4 workers, who contracted it in connection with their researches in the course of official duty. The others are Dr. T. B. McClintic, W. E. Gettlinger and G. H. Cowan.

CALIFORNIA HEALTH INSTITUTE

THE Northern California Public Health Association will hold a Public Health Institute in San Francisco, May 28 to June 8, inclusive. The institute will be conducted by Dr. Haven Emerson, Professor of Public Health Administration, Columbia University, New York, N. Y.

VETERAN OF YELLOW FEVER CAMPAIGN

ANOTHER survivor of the yellow fever experiments conducted by Walter Reed and his associates in the U. S. Army in Cuba in 1901 has been found. He is James Hildebrand, of Atlanta, Ga., and is 73 years of age, and almost entirely incapacitated by tuberculosis. The medical board at Gainesville, Ga., gave him a pension as a Spanish War Veteran of \$50 a month, on which he and his widowed sister live.

Recently in Congress, the Copeland-Wainwright bill was introduced to provide for these survivors or their dependents, regardless of their military rank or civilian status.

REGISTRATION AREA DRIVE IN TEXAS

IN the special drive being made by Dr. J. C. Anderson, state health officer, to bring Texas in the vital statistics registration area, each justice of the peace throughout the state has been asked to act as local registrar in his own precinct.

PERSONALS

- DR. JAMES W. LOUGHLIN has been appointed health officer of the third district with headquarters at New-castle, Me., to succeed Dr. George E. Parsons, who has resigned to enter practice at Millinocket, Me.
- WALTER D. THURBER has resigned because of ill health as executive secretary of the Maine Public Health Association, after 7 years' service, and has moved to California.
- DR. PAUL PREBLE has been loaned by the U. S. Public Health Service to the Maryland State Department of Health to take charge of the Bureau of Vital Statistics pending the selection of a physician to that position; Dr. Preble will continue his work at the Johns Hopkins School of Hygiene and Public Health while with the State Department of Health.
- DR. GEORGE G. EITEL bequeathed to the University of Minnesota \$80,000 to provide a fund for needy medical students and a loan scholarship.
- DR. FERDINAND C. HELWIG has been appointed full-time pathologist to St. Luke's Hospital, Kansas City, Mo.
- DR. LOUIS J. WOLFORD, St. Louis, has been appointed to the Missouri Nurse Examiners Board by the governor to succeed the late Dr. Edward W. Saunders.
- DR. JESSE A. KING, Ojai, Calif., has been appointed health officer of Ventura County to succeed Dr. Adolph A. Maulhardt.
- DR. EDWIN O. PALMER has been appointed superintendent and business manager of the Hollywood Hospital, Los Angeles, Calif.
- DR. FRANK E. McCULLOUGH has been appointed city health officer of North Sacramento, Calif., to succeed Dr. Archibald A. Atkinson.
- DR. CHARLES O. PROBST, Columbus, O., has been appointed medical director of the Franklin County Tuberculosis Sanatorium, succeeding Dr. Stephen Douglass, resigned.
- HEALTH DEPARTMENTS of Hamilton and Butler Counties, O., have combined with Dr. Clifford J. Baldridge as health officer.
- DR. WM. M. HARDY, assistant secretary of the state medical association, has been elected city health officer of Nashville, Tenn.
- DR. HUGH W. WILLIAMS has been elected health officer of Sparta, Wis., to succeed the late Dr. Vernon W. Stiles.
- DR. GUSTAVE WINDESHEIM of Kenosha, Wis., has been elected president of the State Board of Health to succeed Dr. Otho A. Fiedler whose term expired.
- DR. THOMAS J. CHARLTON has been appointed to succeed Dr. Craig Barrow as physician-in-charge of the Georgia Infirmary, Savannah, Ga.
- DR. GUY G. LUNSFORD, Weston, Ga., has been appointed health officer for Crisp County.
- COL. ALBERT A. SPRAGUE has accepted the chairmanship for the Chicago division of the Leonard Wood Memorial for the Eradication of Leprosy.
- DR. LANG A. MITCHELL has been appointed county health officer of Payne, Okla.
- DR. PETER PAUL BARRON has been appointed health officer of the city of Dorris, Calif. to succeed Dr. Sanford W. Cartwright.
- COL. BAILEY K. ASHFORD, medical corps, U. S. Army, has been appointed by the government of Porto Rico as its representative in the International Congress of Tropical Medicine and Hygiene to be held at Cairo, Egypt, December 28.
- DR. GEORGE D. HEATH, JR., has been appointed health commissioner of the city of Bloomington, Ill.

GEORGE A. COLLINS has resigned as health officer of Denver, Colo.

DR. F. BOWMAN, formerly epidemiologist for the Wisconsin State Board of Health, has been appointed health officer for Madison, Wis.

DR. FREDERICK C. ANNABEL, health officer of the town of Elmira, Chemung County, N. Y., for twenty years, died on March 10 from pneumonia.

DR. C. R. BOWEN, health officer of the consolidated health districts of Almond and Alfred in Allegany County, N. Y., died February 27 of heart disease. The fact that he served as health officer of Almond for many years prior to 1904 places him as one of the oldest health officers in point of service.

MILDRED G. SMITH, R.N., formerly Educational Agent of the Minnesota State Department of Health, has been appointed Staff Associate of the National Society for the Prevention of Blindness, with headquarters in New York, N. Y.

DR. J. P. BAKER died at Findlay, O., on February 14. He was an outstanding figure in public health work, and was a member of the board of directors of the Ohio Public Health Association, and president of the Board of Health of Findlay.

DWIGHT S. ANDERSON, publicity assistant, National Tuberculosis Association, has joined the staff of Will, Folsome and Smith, hospital financial directors.

LOUISE FRANKLIN BACHE, formerly of the Syracuse Department of Health and Syracuse Community Chest, is now director of publicity of the National Probation Association.

DR. CHARLES BOLDUAN has been appointed director of the Department of Public Health Education, New York City Department of Health.

AROLD R. HANCE is staff artist of the Michigan Tuberculosis Association.

POSITIONS WANTED

Services of thoroughly qualified graduate sanitarian soon will be available. Experienced in state and municipal public health work, housing, sewerage and sewage disposal, social surveys, municipal waste collection and disposal, sanitary inspections, reports, investigations, etc. Excellent at organization and administration. Let's get together and talk it over. Address 50 W. F.

GRADUATE CIVIL AND SANITARY ENGINEER desires change. Two years as assistant and five years as chief engineer of State Health Department. Also teaching experience in recognized engineering school. Age 31, married. Will consider any kind of responsible employment including teaching sanitary engineering subjects. References furnished upon request. Address 51 F. P.

DIRECTOR OF LARGE PUBLIC HEALTH LABORATORY desires change of position. College graduate. Has organizing and administration ability. Trained and experienced in all forms of laboratory procedure. Address 52 M. C.

Responsibility of Government in Public Health Work*

E. L. BISHOP, M. D., FELLOW A. P. H. A.

State Health Commissioner, Nashville, Tenn.

REASONING primarily from an economic point of view, it can be shown that the human element is the only variable in the equation producing the sum total of a nation's wealth. The total quantity of coal, iron, water power, soil fertility and other natural or physical resources remain essentially the same unless modified by man. Man's ability to convert these resources into products capable of serving humanity largely determines the sum of usable wealth. Man's ability to work therefore, is the variable directly influencing the economic welfare of a community, state or nation. Man's health directly and radically influences his ability to work and produce.

Disease ridden communities are usually poverty stricken communities, which concern not only the communities themselves but the state and nation in which they are found. Can there be a more fundamental responsibility of government, considered from an economic standpoint alone, than the responsibility to serve and protect the public health? If it be granted that we have the responsibility, how may it best be discharged? Certainly there must be an organization to act as the agency of government in fulfilling this responsibility just as other governmental organizations act in fulfillment of their governmental responsibilities. Moreover, organization for health work must follow the lines of governmental organization.

The three elements of government in America are federal, state and local. Each unit of government should discharge that part of the

* Read before the Health Officers Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

responsibility which its opportunities and station in the whole scheme of government especially qualifies it to fulfil.

Public health administrators have, in recent years, come to a definite realization of this principle. For many years the federal government has efficiently performed its function, or at least a part of its function, and states have gradually developed efficient organizations. Within quite recent years, we have found it impossible to succeed unless we develop local health organizations. The South, incidentally, has led the way in this latter development by placement of a major emphasis on full-time local health departments.

The influence of the U. S. Public Health Service is indispensable in this country, (1) as an agency dealing with foreign and interstate problems, (2) as a coördinating influence, (3) a research body, and (4) a stimulant to the development of health activity by state governments. It addition, it has a fifth and vital responsibility to deliver expert consultant service to state health organizations, much as the state gives similar service to its local governments.

A state health department, being one degree nearer the individual citizen, has greater authority than any other jurisdiction and a more intimate relation to local health departments than the federal government. It may utilize the police powers of the state to assist in discharging its responsibilities. Even here, economic administration demands that the state health organization should, though holding central authority, delegate the fullest possible authority to local health organizations in handling local affairs. The state has a double function in the discharge of its responsibility: First, it must act as a stimulant and a coördinating agency in the development and in the work of local health departments whether county or municipal. Second, with the development of a sound local health organization, the state department must maintain a service for consultation and for supervisory activity in connection with the programs of the local health departments.

The local health department is that agency through which government delivers adequate health service to the community. Preventive medicine is an activity concerned with the individual and the community. The federal government cannot maintain an organization reaching every individual and protecting every community with adequate service. Not only would such an organization fail; but in this country of local self government such a situation would not, and should not be tolerated. It is but slightly less absurd to expect a state health organization to render direct health service to each individual community. We expect this of no other state department.

Reasoning, then from this point of view, it would seem that one of

the most important and one of the most immediate responsibilities of government in protection of public health is that of providing at the earliest possible time for wide extension in the development of reasonably adequate local health service, that the direct health service so essential in the protection of public health may be rendered in the proper measure. Unless this is done, neither the federal nor state departments can function effectively and neither can give that measure of service to the nation or the commonwealth that it should give, for there will be no local agency through which it may reach the individual citizen. Hence, both the federal and state governments should concern themselves immediately with preparation for the expansion of local health service. To the extent that they fail in so directing their activity, they fail in fulfilling their major responsibility.

Municipal health organization while yet far from ideal has progressed much more satisfactorily than has rural health organization, due to the urgency of health problems and the concentration of wealth which makes purchase of health service possible.

Rural health organization is confronted by two major problems, the first being the difficulties of financing, and the second that of securing properly trained personnel. Preventive medicine is a specialty of medicine requiring greater special training than the other medical specialties, for it draws upon the whole sum of human knowledge, the natural as well as the medical sciences. With increased demand, however, an increase in trained personnel will take place and this difficulty will be lessened.

Reasonably adequate health service through local health organization is wholly beyond the purchasing power of many local units of government. In the East where there is a high concentration of wealth, this is due to the smallness of the unit of local government. Here it can and will be solved by uniting townships into county or district health departments. In the South, where the county is the basic unit of local government, it may be generations before some counties have it within their power to buy a reasonably adequate health service.

Consider the problem of a county with a population of 2,600 and an income of less than \$15,000.00 per annum—How may such a county buy health protection? The citizens of this county have as much right to expect protection as have the citizens of a county with an income of a million or more. It is the responsibility of the federal and state governments to develop a type of health organization that will meet these economic difficulties, and some progress is being made to that end.

The county health unit or county health department is applicable to a fraction of our southern counties, and to combinations of town-

ships in other sections of the country. Another solution must of necessity be found for some of our southern counties. Various ideas have been proposed. It is well recognized now that the state should coöperate financially with the county, at least during the early history of the county health department. It is the usual thing for the state department of health to provide one-half of the budget for the first year's operation, the funds for this appropriation being derived primarily from state appropriations, but also from federal appropriations and commitments by other agencies. In point of fact both the state and federal governments should participate permanently in the budget of the local health department, since such a procedure accomplishes several quite desirable purposes.

In the first place an equitable taxing system has never yet been devised. Concentration of wealth into urban areas penalizes rural areas, yet rural health problems are complex and more expensive to administer per capita than urban health problems. Hence, distribution of the financial burden is justifiable for the rural area, the state and nation being either directly or indirectly benefitted by well organized local health work.

In addition to this objective, the coöperation of all three elements of government in carrying out the local health program makes for a coördination of health activity the country over. The knowledge of one service becomes the property of all services; elements in the program of one service become parts of the activity of other services. Still another most desirable objective which may be achieved through this coöperation is the stabilization of local organization. The county health department has proved itself as an element in our scheme of public health administration and it is very desirable for the three elements of government to participate in the development and expansion of local health service.

Southern state governments are rapidly assuming this responsibility. The federal government has not yet developed the degree of coöperative activity with states in this respect that it should develop. The total appropriation for this purpose to the U. S. Public Health Service is \$85,000.00 per annum. Tennessee has appropriated exactly this amount per annum for the current biennium, yet Tennessee has only begun the development of its local health program.

As has been indicated, some other method than the county health department must be found to serve the needs of smaller and poorer counties. Some authorities have advised increased subsidies from the state and perhaps federal appropriations. Others have suggested district health organizations, and it has even been said that in extreme

instances the state should assume the entire cost. The latter proposal is entirely unsound from the standpoint of administrative practice. It would do no more than teach the community dependency. It is probable that the final solution will come through a combination of the suggestions involving combinations of local governments and increased subsidies from the state. Certainly this seems to be the more sound and promising point of view. The principles involved have ample precedent both for the federal and state governments in provisions that have been made for the development of educational activity, for the improvement of agriculture, and for the construction of roads. Certainly no one can dispute the fact that the welfare of one community affects the welfare of other communities. It is equally true that the welfare of the country is but the sum of the welfare of its communities and therefore state and federal governments have a definite responsibility in the welfare of every community.

SUMMARY

The federal government should protect the nation from menace from without; should stimulate the states to an efficient state health organization; should serve the states through the rendition of expert consultant service; should deal with matters involving state relations, one with the other; and should coöperate through the state governments in the development of local health organization, especially during the formative stage of this activity.

The state government should protect itself against danger from without in so far as it may; should stimulate and assist local governments in the development of efficient whole-time health work; should give expert consultant service to the local health departments; and serve as a coördinating agent in the development of local health programs by welding these programs into one for the state as a whole.

The local health department should render that measure of direct service to the community which is required for protection against diseases and for the promotion of health. It should demand of its state government that the state render service which it can and should be expected to provide. For example, a small health department needs no sanitary engineer, yet has occasional problems involving such service; it needs no expertly trained epidemiologist, yet not infrequently requires the services of such a person for a short period of time. All three elements of government must concern themselves with research either in the field or in the laboratory, that better methods may be evolved and that knowledge of the causes and conditions of both health and disease increase both in extent and practical application.

Thermal Death Point of Streptococci*

WILLIAM H. PARK, M. D., FELLOW A. P. H. A.

Director, Health Department Laboratories, New York, N. Y.

THE investigations forming the basis of this paper were undertaken because of the expressed wish of some of the members of the Association that a larger number of strains of pathogenic streptococci from varied sources be tested as to their thermal death point at 30 minutes' exposure, before a final decision be made as to the proper temperature necessary for commercial pasteurization.

In order that we may have fresh in mind the previous work on streptococci let us summarize the results of the rather recent elaborate investigation by Ayers.

In 1918, Ayers¹ studied a number of streptococci as to their thermal death point. Cultures of 5 were completely killed after an exposure of 30 minutes to a temperature of 140°, 12 at 135°, 5 at 130°, and 5 at 125° F. He also tested 6 non-hemolytic varieties of streptococci derived from pus from the pleura, scrotum, elbow joint or the blood. These were not killed when exposed for 30 minutes to 140° F. They required heating to temperatures as high as between 55° and 60° C. These are varieties, however, which are not known to have been communicated through milk to man. From Ayers and Johnson we also have the knowledge that among streptococci obtained from the cow resistant strains of streptococci are found. Forty-six of 139 such strains required an exposure of 30 minutes to temperatures of 71.1° C. (160° F.) to 73.9° C. (165° F.) to cause their death. These streptococci, however, so far as known, are not pathogenic to man.

Summing up the results of these investigations we find a small portion of the strains of hemolytic streptococci which may be transmitted by milk and are pathogenic to man, are more resistant than the majority and withstand heating to a temperature of 135° F. for 30 minutes, but not one to a temperature of 140° F. for 30 minutes. The remainder are killed at temperatures ranging from 125° to 135° F.

We now turn to the present investigations, the object of which is, if possible, to satisfy ourselves, by testing the thermal death point of a large number of hemolytic streptococci obtained from human infections, what degree of temperature is sufficient to destroy the most

* Read at a Special Session on Milk of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 18, 1927.

resistant in 30 minutes. Our present information leads us to believe that the diseases shown to have been transmitted through milk by means of streptococci have always been due to the hemolytic varieties.

The few non-hemolytic strains believed to have caused occasional human infections, have been through the taking of food products such as cheese. These so-called "green" streptococci would require much higher temperatures or much longer exposures, so that from the point of view of pasteurization it would be impracticable to safeguard against them, unless they were a very real danger. The streptococci utilized in our tests were 100 strains obtained from the following sources:

Source of Strains	Number of Strains
Cases of	Tested
Septic Sore Throat	20
Tonsillitis	20
Scarlet Fever	18
Mastoiditis	9
Glandular fever	7
Erysipelas	18
Other sources	8
	<hr/>
Total hemolytic strains	100

METHODS USED IN TESTING THE THERMAL DEATH POINT

The First Method was to fill vials with about 10 c.c. of sterile milk and place them in a water bath, the water of which was somewhat higher than the desired temperature. Then the milk in the vials and the water in the water bath having reached the desired temperature, 0.05 c.c. of a blood broth culture of the strain of streptococcus to be tested was injected into the milk and the vial stopped by a rubber cork already heated to the same temperature. The stoppered bottle was then submerged in the heated water for the required times. It was then removed and the contents immediately cooled by pouring the contents into an ice-cold 100 c.c. bottle which was immediately packed for a few minutes in cracked ice. The bottle with its contents was then removed and placed in the incubator at 37.5° C. for approximately 42 hours. The milk in the vial was then tested for viable hemolytic streptococci on blood agar plates.

The individual strains were also tested in a slightly different way by filling the bottles with water and covering them while submerged with softened parchment. This made it possible to be certain that no air pocket was present. The culture of streptococci was injected after piercing the parchment with the needle of the syringe holding the culture.

The Second Method approached the actual pasteurizing process—250 c.c. of milk held in a bottle at the desired temperature was inocu-

lated, and then after a moment's shaking discharged into a funnel heated to the same degree, and through this into a lead coil submerged in water held at the desired temperature. At the proper time the submerged outlet of the coil was raised, the metal stopper removed, and a sample taken. The end was then plugged, plunged in boiling water, and dropped back until the next sample was taken. For this method a large number of strains were mixed together.

Further—through the kind coöperation of Dr. Bundesen—Dr. Tonney, Assistant Commissioner and Director of the Chicago Department of Health Laboratories, subjected 100 strains of hemolytic streptococci derived from similar cases in Chicago to tests carried out by the method of the submerged vials. The results of these tests will be given first.

Thermal death point in milk of 100 strains of hemolytic streptococci exposed at 20 and 30 minutes as reported by Dr. Tonney were as follows:

Sixty strains (sources—milk 10, epidemic sore throat 1, ears and throats of scarlet fever patients 10, throats from cases of contagious diseases 38, and University of Chicago Laboratory 2) were killed after an exposure of 30 minutes to 135° F. Of the remaining 40, there were 2 killed by an exposure to 138° F. for 30 minutes and 38 were killed after exposure to 140° F. for 30 minutes, but probably not killed after exposure of 20 minutes.

The sources of the more resistant 38 strains were—milk 4, epidemic sore throat 1, University of Chicago 1, contagious disease wards 32.

Dr. Tonney wrote me that he did not test the milk in the vials for hemolytic streptococci that seemed to have a growth after 10 and 20 minutes' exposure as his interest was mainly in the 30 minutes' exposure. As some of those which were exposed to 140° for 30 minutes and showed growth in the milk on testing were found to have no living hemolytic streptococci, it is probable that if the milk in the vials heated for 10 to 20 minutes had been tested, the growth might have been shown to be due to other bacteria.

Results obtained in New York City Laboratories were as follows:

Cultures of streptococci from every one of the 100 strains were killed after 10 minutes' exposure to 140° and after 30 minutes' exposure to 138° F. Thirty combined cultures in milk when passed through the lead coil were killed after 30 minutes' exposure at 136° or 20 minutes at 138° or 10 minutes at 140° F. The destruction of most of the streptococci was surprisingly rapid when heated to 138° F. in milk.

Thus, 25 mixed cultures of erysipelas strains added to milk, so that 1 c.c. contained about 10,000,000 streptococci showed no growth after

5 minutes' exposure, either in blood plates immediately inoculated with 1 c.c. or in plates inoculated from 3 c.c. of milk after 42 hours of incubation.

PATHOGENIC NON-HEMOLYTIC STRAINS OF STREPTOCOCCI

In the issue of August 6, 1926, of the *Public Health Reports*, Linden, Turner, and Thom report two outbreaks of food poisoning due to the eating of cheese. In all, 31 persons suffered from an attack of pains in stomach, nausea and diarrhea. Samples of the two lots of cheese showed enormous number of bacteria. These were mostly short non-hemolytic streptococci. Milk cultures of these streptococci caused illness when fed to cats.

They report that of 3,500,000 of these organisms subjected to 143° F. for 30 minutes, 6,100 survived, but that of 1,000,000 exposed to 145° F. for 30 minutes none survived. In our tests they have been more resistant.

In our laboratory Miss Oldenbusch subjected the culture to temperatures of 143° and 145° F. with the following results:

TIME OF EXPOSURE	AT	143° F.	145° F.
		Streptococci in 1 c.c.	
30 minutes		4,000,000	2,500,000
45 "		1,950,000	450,000
60 "		1,440,000	48,000
75 "		14,000	700
90 "		900	0

The infected milk before heating when plated developed about 40,000,000 colonies per c.c.

There are at least two important reasons why the existence of these heat resistant non-hemolytic streptococci have little or no bearing on the question of the proper temperature to be used in the pasteurization of milk. The first is that no outbreak of milk infection has been traced to them, the second that the temperature required to kill them is so great that it would damage the taste and appearance of the milk to a degree which would make it much less desirable as a food.

I believe no one would suggest that pasteurization of milk be carried on for 90 minutes at a temperature of 147° to 148° F.—the two degrees being necessary as a margin of safety.

THERMAL DEATH POINT OF BRUCELLA ABORTUS

The importance of infections with this microorganism having been so recently appreciated, little work has been reported upon its resistance to heat. The results of the following experiment are given so as to complete the study of the thermal death point of pathogenic bacteria transmitted through milk. These tests were carried out in the New York City Department of Health Laboratory by Carolyn Oldenbusch.

Sterile milk was bottled in 9 c.c. amounts and heated to a temperature of 1° C. above test temperature. One c.c. of a suspension of 13 strains of *B. melitensis* and *B. abortus* (of human, bovine and swine origin) was added to each bottle which was then submerged in a water bath at the appropriate temperatures, for the desired length of time.

On removing from the water bath, bottles were plunged into cracked ice and quickly and thoroughly chilled. Four plates were then made from the milk, and again after the milk had been incubated for 48 hours at 37° C. Controls showed there were 5,000 billion organisms per c.c. of milk.

At 140° F. the cultures survived $7\frac{1}{2}$ minutes, but were killed at 10 minutes. At 142° F. they survived 5 minutes and were dead at $7\frac{1}{2}$ minutes, while at 145° F. the milk was sterile at the end of 5 minutes' heating.

SUMMARY

Two hundred strains of hemolytic streptococci obtained from different cases of septic sore throat, scarlet fever, erysipelas and other diseases known to be due to hemolytic streptococci and transmitted at times through milk were tested as to their thermal death point while in milk after 30 minutes' exposure.

One-half of these were examined in the laboratories of the Chicago Department of Health under the direction of Dr. Tonney and one-half in the laboratories of the New York City Department of Health.

Cultures from every one of the 200 strains were killed by an exposure to 140° F. for 30 minutes. The majority of strains were killed at a temperature of 136° F. or less.

The resistant, probably pathogenic, non-hemolytic streptococcus found in cheese was not killed after 75 minutes' exposure to 145° F. but was killed after 90 minutes.

Cultures of *B. melitensis* and *B. abortus* were killed after 10 minutes' exposure at 140° F.

Progress in the Control of Pollution by Industrial Wastes*

ALMON L. FALES, FELLOW A. P. H. A.

Metcalf and Eddy, Engineers, Boston, Mass.

IN 1916, the Committee on Sanitary Control of Waterways presented a report¹ dealing with the fundamental principles involved in the sanitary disposal of sewage and industrial wastes and recommending a "Code of Regulations for the Sanitary Control of Waterways." Subsequently that committee presented a "Bibliography on Industrial Wastes," but this was not published. No further reports have been made by that committee which has now been consolidated with the Committee on Sewerage and Sewage Disposal and Committee on Sludge Disposal to form the Committee on Disposal of Sewage and Industrial Wastes. As a member of the new committee, the writer has been requested to present a paper on progress in the control of pollution by industrial wastes.

Lines of Progress in Control of Pollution—Considerable progress has been made in recent years in the control of pollution by industrial wastes. This progress has been along several different lines including discussion, investigation, coöperation, litigation and legislation. Some of the more important developments along these lines are outlined in this paper.

Papers and Symposia on Industrial Wastes—Numerous papers on different phases of the industrial wastes disposal problem have been published in society journals or proceedings and in the technical press. Symposia on industrial wastes have been held at meetings of various technical societies including the American Chemical Society, American Institute of Chemical Engineers, American Water Works Association and American Society of Civil Engineers. The subject was also discussed at the International Conference on Sanitary Engineering in London in 1924.

At the meeting of the National Health Congress at Atlantic City, N. J., in May, 1926, a session on domestic and industrial wastes in relation to water supply was held under the joint auspices of the Public

* Presented to the Public Health Engineering Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 20, 1927.

Health Administration Section and the Public Health Engineering Section of the American Public Health Association and the New Jersey Sanitary Association. At this session, papers were presented by eminent authorities on administrative problems, legal principles involved, and solutions of the problem of control of industrial wastes pollution. These papers, together with discussions of the same were published in the *American Journal of Public Health*.²

Reports of American Water Works Association Committee on Industrial Wastes in Relation to Water Supply—Industrial wastes in relation to water supply has been the subject of investigation by a committee of the American Water Works Association, which has made four progress reports.^{3,4}

Monograph by Legislative Reference Service—A monograph on the Pollution and Obstruction of Navigable Streams in the United States by Sewage and Industrial Wastes has recently been prepared by George J. Schulz of the Legislative Reference Service of the Library of Congress.⁵

A large part of this monograph is devoted to the subject of treatment of industrial wastes. Several different kinds of wastes are dealt with and the importance of recovery and utilization of valuable by-products is stressed.

Control by State Boards of Health—The control of stream pollution in the United States has been vested very largely in the state boards of health, although information obtained in 1921 by the American Water Works Association Committee⁶ showed only 5 states where the authority was ample in all respects, and in nearly all cases enforcement of the laws was materially hampered by insufficient appropriation for adequate field and laboratory forces. Since that time, state boards of health in general have been strengthened in these respects and have become more active in the matter of stream pollution control. The International Health Board of the Rockefeller Foundation⁷ reports that whereas in 1915 only 18 state boards of health in the United States had divisions of sanitary engineering, at the close of 1926 all but 4 states had established such divisions.

Pennsylvania Sanitary Water Board—State authorities, other than boards of health, which have had to do with stream pollution control, include commissions on fisheries, boards of conservation and special boards. In Pennsylvania, the control of stream pollution is vested in the Sanitary Water Board created in 1923 for the purpose of coördinating the duties and authority of various branches of the state government and composed of the Secretary of Health, the Secretary of Forests and Waters, the Commissioner of Fisheries, the Chairman of

the Public Service Commission and the Attorney General.* This board has created an Industrial Wastes Section to give particular attention to the problem of control of pollution by industrial wastes.

Classification and Zoning of Streams—The Sanitary Water Board of Pennsylvania has undertaken to classify the streams of the state with a view of maintaining in good condition those (Class A) that are still satisfactory for water supply after chlorination only; controlling or eliminating pollution on certain other streams (Class B) for the protection of public health and animal and aquatic life and use for recreational purposes; and of permitting the discharge of sewage and industrial wastes into certain streams already polluted (Class C) provided such discharge will not create a public nuisance or menace to health. In Ohio also provision has been made for the zoning of the waters of the state.

The Ohio Stream Pollution Act of 1925—Most state boards of health have incomplete authority over pollution by industrial wastes. The Ohio State Department of Health is an exception to the rule. An act passed by the General Assembly in 1925 provided, among other things, for the approval of the State Department of Health of any new or increased discharge of industrial wastes, for general supervision by the department, of the operation and maintenance of industrial wastes treatment plants, and for the adoption by the department of such regulations as may be necessary for preventing undue pollution of streams.

Interstate Agreements—There is no general provision in this country for the control of pollution of interstate streams as in the case of the rivers boards in Great Britain and the drainage districts in Germany.¹⁹ Mutual agreements with respect to the policy of controlling pollution of interstate streams have been made by the health departments of certain states including Pennsylvania and New Jersey; Pennsylvania, Ohio, West Virginia, Kentucky, New York, Maryland, Indiana, Illinois and Tennessee; and Ohio and Michigan. These interstate agreements have proved very beneficial in the control of pollution by industrial wastes.

Coöperation with Industry—The Sanitary Water Board of Pennsylvania adopted the principle of coöperating with industry in the solution of industrial wastes disposal problems. An agreement between the board and companies operating tanneries in the state established in 1924 the Tannery Waste Disposal Committee of Pennsylvania, which has been carrying on investigations to determine the best methods of treating tannery wastes. In a similar manner, the Pulp

* The Sanitary Water Board, as now constituted, consists of the Secretary of Health, the Secretary of Forests and Waters, the Commissioner of Fisheries and 3 members appointed by the Governor.

and Paper Waste Disposal Committee of Pennsylvania was created in 1925 and, as a result of coöperation with the American Paper and Pulp Association, the National Committee on Stream Pollution for the Pulp and Paper Industry was formed in 1926.

In Ohio, conferences have been held by the State Department of Health with representatives of paper, beet sugar, canning, milk and steel industries, in an effort to secure voluntary action by industry in a study of wastes treatment problems. It is reported that this effort has met with considerable success, several committees having been formed for the purpose of carrying out the recommendations of the Department of Health.

The State Board of Health of Wisconsin has been coöperating with industries in the investigation of the treatment of pea cannery wastes, and the wastes from pulp and paper mills. The results of the investigations are given in a Special Report on Stream Pollution in Wisconsin prepared by the Bureau of Sanitary Engineering of the State Department of Health and issued in 1927 as a Joint Report of the Conservation Commission and State Board of Health.

Efforts to secure the coöperation of industries in the solution of wastes treatment problems have also been made by the state departments of health of Michigan, Maryland and other states. The cases cited show clearly the trend towards solving problems of industrial wastes treatment by coöperation with industry.

Phenol Wastes Conference of States on the Ohio River Watershed
—The serious and widespread troubles from tastes and odors imparted to water supplies by the so-called phenol wastes from gas and by-product coke manufacturing, led the Surgeon-General of the U. S. Public Health Service, on January 29, 1924, to call together for a conference on the subject, representatives of departments of health of the states where complaints of pollution from this source had originated. This conference requested the U. S. Public Health Service to further investigate the problem with respect to its public health aspects, and the Bureau of Mines to investigate it in its industrial aspects, particularly in regard to practical methods of eliminating or treating the wastes at their source. These governmental departments have since made reports on the subject.

Following this conference, the Phenol Wastes Conference of States on the Ohio River Watershed was formed. This organization has held several conferences, and much progress has been made in controlling pollution by phenol wastes. On September 27, 1926, a committee was appointed called the "Board of Public Health Engineers, Ohio River Basin," and composed of the chief engineers of the departments of

health of eight states on the watershed, this committee to act in an advisory capacity.

Melcroft Coal Co., Acid Mine Drainage Case—Another source of serious and extensive pollution of water supplies is the acid drainage from coal mines. The Bureau of Mines has recently issued a report on the subject. The outstanding development with respect to pollution by acid mine drainage is the court decision in the so-called Melcroft Coal Co. case.*

In 1920, the Mountain Water Supply Co. of Pennsylvania, a subsidiary of the Pennsylvania Railroad, filed a bill in equity against the Melcroft Coal Co. and some 20 other coal mining companies to restrain them from permitting mine drainage to flow into Indian Creek or its tributaries. The case was tried before the Fayette County Court which, on December 26, 1922, rendered an opinion that the discharge of mine drainage by the defendant coal companies was a proper and natural use of their lands and constituted a right of property of which they could not be deprived except by due process of law, and dismissed the case.

The case was appealed to the Supreme Court of Pennsylvania, which, on September 29, 1924, rendered an opinion that the lower court was in error, and that "the defendants have no right of any kind to drain their mine waters into the stream, considering the public use which is made of its waters, and that their doing so constitutes a nuisance which must be restrained." The defendants were enjoined from discharging mine waters into Indian Creek above the dam of the Mountain Water Supply Co. after the expiration of 6 months from the date of entry of the decree.

Following the decree of the Supreme Court of Pennsylvania, the defendant coal companies sought to have the Supreme Court of the United States review the case, but after hearing briefs and arguments, the Supreme Court refused to do so.

In conformity with the decree of the Pennsylvania Supreme Court, an order was issued by the county court giving the coal companies until July 30, 1925, to cease discharge of mine drainage into the stream. On July 27, 1925, 4 of the principal defendants filed a petition in the county court setting forth a plan for disposing of their mine waters and asking for an extension of time. After hearing the arguments, the court suspended the rule which left these companies in contempt of court.

Contempt proceedings were brought against the other coal mining

* Information in regard to the progress of this case has been furnished by Wm. McCaleh, General Superintendent of Water Companies of the Pennsylvania Railroad.

companies and a decree was handed down declaring all the defendant companies, excepting the 4 referred to above, in contempt of court and ordering them to seal their mines within 30 days. Some of the companies complied with the order of the court but about 15 companies operating small mines failed to do so and the sheriff was instructed to seal these mines, which has been done. While the sealing did not entirely stop the flow of mine water, it effected a material reduction.

The 4 principal defendants joined together to incorporate a drainage company which has built a tunnel and flume about six miles long discharging the mine drainage below the dam of the water company.

Oil Pollution Act of 1924—Numerous bills to prohibit the discharge of industrial wastes into navigable waters or their tributaries were introduced in Congress in 1923 and referred to the Committee on Rivers and Harbors which held extensive hearings. The outcome was the so-called Oil Pollution Act of 1924."

This act provides that except in certain cases of accident or emergency or as permitted by regulations which the Secretary of War is authorized to prescribe, it shall be unlawful to discharge oil into or upon the coastal navigable waters of the United States from any oil burning or oil transporting vessel. The administration of the Act is placed into the hands of the War Department and penalties are provided for violation of the Act.

Report of War Department—An investigation of the pollution of navigable waters was made by the War Department in compliance with the Oil Pollution Act of 1924, and a report presented to Congress on June 4, 1926."

In addition to domestic sewage, the report lists the industries which are the sources of the more injurious polluting substances. These sources of pollution are discussed and the effects on navigation or commerce and on fisheries are described. A table is given showing navigable waters affected by pollution, the principal sources of pollution and the injurious effects. A summary of the findings is included and the existing federal laws relating to the pollution of navigable waters are summarized and data are given with respect to state control of pollution. The report states that industries are coöperating with local authorities in a study of the problem and devising methods by which injurious substances in the wastes can be recovered or rendered less harmful before discharge into the waters.

No federal legislation was recommended at this time with respect to pollution in general nor in regard to acid-mine drainage in particular. With respect to oil pollution, it was recommended:

. . . . that the oil pollution act of 1924 be made applicable to the discharge of oil from any source, into or upon the coastal navigable waters of the United States, or into or upon any of the Great Lakes, their harbors and their connecting channels.¹³

International Conference on Oil Pollution—Pursuant to a joint Resolution of Congress, a Conference of Maritime Nations was held at Washington, June 8-16, 1926, to consider means for the prevention of pollution of navigable waters by oil from oil burning and oil carrying steamers. Prior to the calling of this convention an Interdepartmental Committee on Oil Pollution of Navigable Waters was formed, which, after investigating different phases of the subject, made a report¹⁴ that served as a basis for the international conference.

The conference reached an agreement with respect to recommendations to the participating governments and adopted a Draft of Convention to take effect upon ratification by 5 of these governments. Various shipping interests and other interested organizations in the United States and Great Britain have agreed that the recommendations of the conference should be voluntarily put in operation.

Present Status of Oil Pollution—It is generally reported that oil pollution conditions have improved decidedly in recent years and, although conditions in many places are still far from satisfactory, the indications are that the oil pollution problem is well on the way to solution.

CONCLUSION

Although considerable progress has been made in the control of pollution by industrial wastes, much remains to be done. By continued scientific investigation of unsolved problems of industrial wastes treatment, by coöperative effort of all interested parties including industries themselves, and by reasonable laws wisely administered, the problem can be solved.

DISCUSSION

MAJOR F. E. DANIELS, FELLOW A. P. H. A.

Chief, Industrial Wastes Section, State Department of Health, Harrisburg, Pa.

ALONG with the work of investigating streams for classification, the Sanitary Water Board is making a critical survey of several streams to determine accurately where and to what extent conditions are unsatisfactory, and to determine reasonable and practicable requirements for industrial waste treatment in order that the powers of assimilation of the stream may be utilized, as well as maintaining the stream in a satisfactory condition. For the State of Pennsylvania to flourish, we must preserve our industries as well as our streams.

The field work of a preliminary survey of about 200 miles of the upper Allegheny River has just been finished and the correlation of the data obtained is now being made. The portion of the river studied extends from Coudersport up through a part of New York State back into Pennsylvania to Franklin. The New York Department of Health coöperated in the study of the New York portion of the river.

The character of the survey was quite similar to that done by the U. S. Public Health Service on the Ohio River, except that the work, other than the routine sanitary chemical analyses, was done in a motorized traveling laboratory. In July and August this laboratory covered a distance of over 3,000 miles.

A similar survey is now in progress on the Schuylkill River between Reading and Philadelphia, a distance of some 60 miles.

Special surveys of the dissolved oxygen of the Brandywine Creek, the Bald Eagle Creek and the Susquehanna River above and below several paper mills have been made in connection with studies on paper mill wastes.

An intensive study of industrial wastes in Bridgeport, Pa., is now going on. These wastes are wool scouring, paper mill, packing house and pickling liquor.

Mr. Fales has referred to the coöperation of the Sanitary Water Board with industry. The Tannery Waste Disposal Committee of Pennsylvania consists of three chief engineers and three chief chemists of companies parties to the agreement, and the chief engineer of the Sanitary Water Board as chairman. The agreement provides for the creation of a fund of \$35,000 contributed by the companies in proportion to the capacity of their tanneries. To date the Sanitary Water Board has contributed considerably over \$8000 toward this fund.

The fund is being expended by the committee in research along three main lines:

1. Investigations in the laboratory to determine the characteristics and relative strength of the 15 wastes which are produced during processes of vegetable tanning of leather.
2. The erection, operation and study of full-scale experimental treatment works, predicated upon the results of the laboratory research work.
3. The study of streams to determine their assimilating capacity for tannery waste, untreated and treated to varying degrees.

In addition to research work in the laboratory and studies of twelve miles of stream below the Instanter tannery, a full-scale experimental sedimentation works was constructed and operated at Instanter.

Due to the closing down of a railroad, that plant had to be abandoned and the committee has constructed a new and improved plant on rather similar principles at Emporium, Pa. The construction of the new plant has practically exhausted the fund.

We are proposing to the companies parties to the original agreement to execute

a supplement which will extend the life of the original agreement and provide for \$25,000 from the companies and not less than \$5000 nor more than \$15,000 from the Sanitary Water Board.

The committee believes it will find reasonable and practicable ways and means for the treatment and disposal of tannery waste.

The second coöperative industrial waste project of the Sanitary Water Board was inaugurated in 1925 by the creation of the Pulp and Paper Waste Disposal Committee of Pennsylvania, consisting of engineers and chemists of that industry and the chief engineer of the Sanitary Water Board as chairman.

The first report of the committee to the board set forth a number of the problems which had already been solved by that industry. In Pennsylvania during the 10 years prior to 1925, 8 mills alone had expended \$2,500,000 for apparatus for the removal of materials from pulp and paper mill waste waters and for research in connection therewith.

For the still unsolved problems and the further improvement of the waters of the state, the committee recommended coöperative investigations.

The Sanitary Water Board then submitted a draft of agreement to the executives of the pulp and paper industry in Pennsylvania and this formal agreement dated November 17, 1926, has been executed by 24 companies who represent about 80 per cent of the entire output in the state. Under the agreement the committee has been enlarged to 15 members to include technical representatives of all types of mills.

Before even considering the subject of further treatment of pulp and paper mill wastes, the committee must first secure reliable scientific data upon the amount, kind and characteristics of the many different waste waters resulting from the manifold and diverse processes of manufacture of pulp and paper. In order so to do the committee has tentatively adopted standard methods for measuring, sampling and testing such wastes.

In accordance with the agreement 8 companies, parties thereto, volunteered the use of their existing laboratory facilities, regular apparatus and chemists. The Sanitary Water Board had preliminary studies made in its laboratory, furnished special apparatus for the 8 mill laboratories and provided training to the mill chemists in certain special tests to assure uniformity of technic as the work is done in the separate laboratories.

The work is being done in a thorough, careful, scientific manner and is bound to yield worth-while results.

In each of the 8 mill laboratories an assistant chemist has been assigned to work on the wastes and these men have been made associate members of the Pulp and Paper Waste Disposal Committee of Pennsylvania. They have in turn been formed into a sub-committee with the chief of the Industrial Waste Section of the Sanitary Water Board as chairman, who is also a member of the main committee. This sub-committee meets once a month to compare notes and discuss ways and means of solving difficulties in obtaining concordant results.

The main committee is kept informed of the work and although it outlines and directs the activities, the sub-committee is free to work out methods and details.

Coöperative work has also been done on laundry wastes and from all accounts, it may be that the same kind of procedure will result with other large industries.

Helpful coöperation of certain industries on the Monongahela, Shenango and Schuylkill Rivers has resulted in a great benefit to water supplies taken from those rivers, by the exclusion from the streams by-product coke oven and gas-house wastes.

The reversal by the Supreme Court of the lower court's decision in the Melcroft Coal Company case was a surprise to many, but it resulted in the collection and discharge of the mine drainage from the principal workings to a point below the water company's dam. Provisions have been made for other companies connecting should they so desire.

Not long ago I made a personal inspection of the valley and found by measurements and tests that the water now escaping from the sealed mines is either negligible in quantity or comparatively small; and that the acid content of the worst discharges is now only 50 per cent of what it formerly was and in some cases the drainage has actually become alkaline. This makes the reduction in total acid discharged daily a very large amount.

F. H. WARING

Chief Sanitary Engineer, State Department of Health, Columbus, O.

AS noted by Mr. Fales, there have been several lines of endeavor between those in charge of the problem of control of pollution of streams and the industrial interests. In Ohio they may be listed as follows:

Investigation—It was necessary to make a stream pollution survey to note what agencies were causing the pollution and to study in detail the industrial processes originating the waste matters.

Legislation—Based upon the preliminary results of the survey, legislation was framed and enacted with a view to curbing and correcting industrial wastes pollution. Responsibility was placed with the State Health Department for this activity.

Coöperation—It was deemed essential that the problem of correcting pollution by industrial wastes be attacked in a coöperative manner. Education of those in charge of industrial operations was necessary to give them a knowledge of what material was causing pollution; research study on the part of industry was needed to bring about changes in processes to minimize, eliminate or change the materials causing the pollution. It was soon realized that experimentation would be required in many instances, and it was further agreed that such research and experimentation should be undertaken by industry.

Groups were formed of manufacturers

having similar processes causing wastes pollution. The problem was discussed with each group and specific instances called to the attention of the group where the pollution conditions were worst. A mutual understanding was reached by which the industry would proceed in the study and experimentation, and in return the health department would exercise a reasonable attitude in carrying out the provisions of legislation when those affected by the pollution demanded drastic action.

ACCOMPLISHMENTS IN TREATMENT AND DISPOSAL

Much progress has been made in the two years, particularly with the groups which have caused the most annoyance in stream pollution. The following will recite the accomplishment by groups.

By-product Coke Industry—The industrial wastes from this manufacturing group consist of crude phenol arising from the manufacture of coke and the refinement of tar resulting from the distillation of coal. Public water supplies in the past have been seriously damaged by reason of an offensive taste and odor of the most far-reaching character. Elimination of the phenol bearing liquids has been determined upon by this group of industry as being the positive answer to the problem. Much water is used in the quenching of hot coke and it has

been possible to eliminate the phenol bearing liquids by utilizing them in connection with the quenching of the coke in a closed system of operation.

There are 16 by-product coke plants in operation or under construction in Ohio, 8 being located on Ohio River watershed and eight others on Lake Erie watershed. Seven of the 8 on the Ohio River watershed have completed the elimination by means of the quench system, and 1 is disposing of the wastes temporarily by pumping them to an abandoned gravel pit for leaching into the ground. Of the 8 on the Lake Erie watershed area, 3 (Cleveland district) have adopted the quench system of elimination, 3 others pond the wastes and do not refine the tar, 1 utilizes a partial recovery process (benzol extraction), and 1 (Toledo) has made no progress. It is fair to state, however, that the plant at Toledo is withholding installing the quench system pending the decision of the city to receive the phenol wastes into the new sewage treatment works, designs for which are now being made.

Paper and Pulp Industry—A national organization of the paper and pulp industry has been in effect for several years. This organization has created a technical committee to cause research with the avowed intention of purifying the streams from paper and pulp wastes. As a result of their researches satisfactory processes have already been effected. In Ohio this problem of pollution by paper mill wastes has not been very acute. A local committee was organized to act for the paper mill interests. Two plants have installed "Save-all" devices, one at Dayton, the other at Chillicothe. It is felt that these installations are satisfactory in solving the problem at the 2 plants mentioned. It is of interest to note that the savings brought about by installing the new equipment have paid for the installation in less than one year's time.

Strawboard Manufacture—At the instigation of the Ohio Strawboard Manufacturers a group has been effected comprising 22 manufacturers and representing all of the strawboard mills in Ohio, Indiana, Illinois and the mid-west states. A committee has been appointed, funds are raised and experimental work is under way at 2 works, Cedarville, O. and Vincennes, Ind. The experimental plant now in operation at Cedarville utilizes the principle of chemical precipitation and chlorination of the waste liquid; the precipitate is maintained by the chlorine in fresh condition; it contains fiber and other matter which is returned for use in the makeup of the strawboard. These studies are still under way to determine amounts of material which can be reclaimed for use in the strawboard. It is also thought that the waste water after separation from the material can be entirely re-used in the process so that the strawboard polluting matter may be entirely eliminated.

The Vincennes experiment is upon the principle of substituting caustic soda for lime in the digestion of the straw. If recovery of the sodium salts can be effected with economy, the pollution problem should also be reduced very greatly, if not entirely, by this method.

Milk and Dairy Industry—This group has an active committee assisted by a consulting engineer for the service of all milk and dairy plants in Ohio. As a result of research, processes of treatment have been determined upon and 3 full-scale demonstration plants have been built. Two of the 3 are in complete operation and the third will soon be in service. The plants now operating are those of the Nestles Food Corporation at Sunbury; and the Chicago Walgreen Company at Holgate. The Toledo Paige Dairy Company at Bluffton will have its plant in service soon. The principle involved in the treatment of milk wastes and as exemplified in these plants, is the collection of the flow in a rela-

tively small capacity equalizing tank and application onto trickling filters immediately, without first passing through any settling or septic tank. Sludge is avoided and odors of decomposition eliminated. The effluent of the trickling filters is sufficiently oxidized to remain stable almost indefinitely. In order to prove economical it has been necessary to separate clean waters from contaminated waters; and to exercise good housekeeping in handling of the milk to eliminate all unnecessary milk discharges.

Acid Iron Wastes of the Steel Industry—A general committee and a technical committee have been formed by the group of steel manufacturers. The technical committee first reported upon several possible plans for eliminating the polluting material. The two ingredients to be cared for are weak acid and ferrous sulphate. The methods reported upon by the technical committee are (1) neutralization and chemical precipitation of the acid and ferrous sulphate as hydrate allowing the whole to flow to the stream; (2) the same as above but accompanied by removal of the precipitated iron hydrate and calcium sulphate by sedimentation; (3) the recovery of the ferrous sulphate by crystallization; and (4) the electrolytic recovery of iron and sulphuric acid.

The studies of the technical committee have indicated that the most probable methods thus far for serious consideration are items (2) and (3). Plants are already in operation recovering ferrous sulphate but the committee does not recommend the wholesale installation of ferrous sulphate recovery owing to the lack of market for its disposal. Therefore, the committee has leaned toward the precipitation of the ferrous sulphate as hydrate as a disposal method.

An experimental plant has been put in operation at the Cambridge works of the American Sheet & Tin Plate Company. The facts concerning the amount

of lime to effect neutralization of the acid and precipitation of the iron as ferric hydrate have been ascertained. Studies are now under way to attempt to find a market for the air-dried ferric hydrate and calcium sulphate, also the calcined and powdered form of the same material. The paint, cement and ceramic industries are being solicited in this regard. The technical committee has advised their membership that this method should be adopted wherever conditions are acute enough to demand immediate action. Obviously the expense of the method is considerable and it is for this reason that the studies are being continued.

The Canning Industry—In 1926 the canning industry of Ohio through its committee and consulting engineer installed and operated an experimental station at the Sears-Nichols Company, Canal Winchester, O. Many methods of treatment were studied. At the conclusion of experiments one method was recommended for universal adoption. In accordance with the program this cannery was to have installed a full-scale demonstration works but owing to the poor season and the financial difficulties of the company no operations were conducted at Canal Winchester in 1927.

Based upon the results of their experiment, however, other canneries have installed portions of the works recommended by the committee and its engineer, pending the establishment of the necessity for further treatment at the particular works involved.

In the meanwhile the New York Canners Association in coöperation with the Ohio canners employed the same engineer to install a full-scale demonstration plant at the largest cannery in New York State located at Albion. The works installed are based upon the Ohio experiment of 1926. Coöperation of the National Canners Association in this demonstration at Albion is effected. Preliminary reports indicate that with cer-

tain modifications of minor nature the New York works are constituted along the lines recommended originally in 1926 experiment. Briefly stated the following principles are involved: (1) Separation of clean waters from contaminated waters; (2) good housekeeping methods to keep at a minimum the waste materials passing into the sewer; (3) installation of fine screens, mechanically operated, in place of sedimentation; and (4) application of the screened liquid to oxidizing filters of the trickling type. The demonstration will determine such details as fineness of mesh, rate of flow through the screens, rate of filtration upon the trickling filters, etc.

Beet Sugar Industry—This group includes 5 beet sugar works in Ohio and 14 in Michigan. The joint arrangement is in effect because 3 of the 5 Ohio companies are also operating in Michigan. Studies are under way by the technical experts of the several companies involved, the research work being subdivided as to particular phases; for example, an installation was made at Ottawa, O., in 1927, comprising a mechanical screen of the self cleansing type to remove the maximum possible amount of suspended matter; this material has a value together with other coarse screenings for returning to the farmers for use as fertilizer. A Toledo company is experimenting with the salvage of the Steffens waste, the most concentrated and troublesome of beet sugar waste, to find out if a by-product material may be made with a saleable value. It is reported that some success has been indicated in the production of a condiment or cheap food for use in Japan and China.

CONCLUSION

In Ohio the State Department of Health has experienced the very best of coöperation with industrial groups. We feel that some of the problems have been solved so that industries now know the details for the correction of stream pollution. Some of the industries have not yet found a sufficiently satisfactory answer to recommend wholesale installations, but are in position to dictate what can be done if the conditions demand correction. Still other industries have not yet organized for effective campaign. However, this is not because they are not willing, but that they have not yet been approached by the health department.

It is obvious that the most important offenders should be taken care of first, and then the lesser offenders invited to enter the campaign. There is also the matter of limited personnel in the health department. It has been deemed wise to concentrate on a few groups constituting the most important, and when these have been established as smoothly working organizations attention will be given to the less important groups.

Our experience has been that much of the remedial measures must come from within the manufacturing establishment; therefore, the technical staff of the industry must certainly be enlisted in an effort to solve the wastes pollution problem. This is particularly true of the large corporations such as the by-product coke and steel industries, paper mill and strawboard industries. In other lines of activity, such as the milk and dairy industry, a large measure of the success is attributed to the employment of outside engineering talent to direct the researches and demonstrations.

Changing Tuberculosis Rates in Michigan*

WILLIAM J. V. DEACON, M. D., FELLOW A. P. H. A.,
GEORGE C. STUCKY, M. D. and DAVID R. BISHOP

State Department of Health, Lansing, Mich.

IN CONSIDERING the changing tuberculosis death rates we believe that a study of the conditions limited to the State of Michigan will be of more value than one covering a larger area. The facts for this study were taken from the death records on file with the Michigan Department of Health.

The death rates from all forms of tuberculosis by years, show a decline from 107.0 per 100,000 population in 1901, the highest rate, to 67.5 in 1925, the lowest rate, with a slight rise to 71.2 in 1926. This decrease from 1901 to 1926 of 35.8 per 100,000, or equivalent to about 33.5 per cent, seems all the more remarkable in that it took place in the face of an enormous increase in the population and through a period marked by war, and the hardships it entailed.

The geographical variation of tuberculosis rates in Michigan is marked. There are 83 counties in Michigan and for the purpose of this study they have been divided into 4 groups, ranging from south to north, the Upper Peninsula forming by itself the most northerly group.

In the Upper Peninsula the highest rate was in Schoolcraft County where the average rates decreased from 343.1 in 1901-1905 to 95.2 in 1921-1925, a decrease of 72.3 per cent. Only one county showed an increase.

In the northern counties one county showed a decrease of 78.8 per cent and all of the counties showed some decrease except two, which showed increases.

In the central counties the decrease was more even and ranged from 26 per cent to 57 per cent but all the counties showed a decrease.

In the southern counties every county showed decreases ranging from 22.7 per cent in Washtenaw to 74.3 per cent in St. Joseph, except Livingston County where the State Sanatorium is located.

All of these groups have shown a decrease in rate during the period

* Read before the Vital Statistics Section of the American Public Health Association at the Fifty-sixth Annual Meeting at Cincinnati, O., October 19, 1927.

under consideration; the rate for the central counties falling over 50 per cent in 25 years, while the southern counties with a decrease of about 20 per cent showed the least decline. The rates for the northern and central groups have been roughly the same, while the rates for the Upper Peninsula and the southern group have also been similar.

In 1901 the rates for all 4 groups were much closer together than they were in 1926. The variation was from 89.0 to 109.8. In 1910 the spread was not any greater, being only from 97.7 to 104.6, but in 1926 the rate varied from 42.6 to 86.4; the lowest rate being less than one-half of the highest.

Table I gives the average rates for 1901 and 1925 for each group:

TABLE I

	Rate Per 100,000 Population 1901-1905	Rate Per 100,000 Population 1921-1925
Upper Peninsula	109.8	81.6
Northern Counties	89.0	52.0
Central Counties	98.6	42.6
Southern Counties	108.5	86.4

We do not believe the decrease is a question of climate but there are two factors which may be of influence: First, there are more sanatoria in the southern group but this would not affect the rate in the Upper Peninsula; second, there is more crowding of population in the lower group.

In 1926 this lower group represented about one-fourth of the area of the state but contained 56 per cent of the population. In this southern group is the city of Detroit with more than one-fourth of the total population of the state. Wayne County in which Detroit is located is now practically one large urban community containing two cities of more than 50,000 population each besides Detroit (Highland Park and Hamtramck) and the most of the tuberculosis sanatoria which serve Detroit patients are located outside of the city but in Wayne County. In 1926 there were 1,450 deaths from tuberculosis in Wayne County.

If we omit Wayne County from the southern group we find that the 1926 tuberculosis rate drops to 72.8 instead of 93.5. This is still far higher than the rates of 42.6 and 52.0 for the central and northern counties respectively. But this is too far above these latter rates to be passed without comment and we have gone further in the attempt to make corrections which will give us the true rate for the southern group.

Leaving out Wayne County, there seems to be no reason why the rate should not approach that of the other county groups for in nativity

and distribution of population these groups are similar to the others. There are no more large cities than in the rest of the state. In fact, the second and third cities in size are not in this group.

But if we study the death rates from 2 of the counties in this group, it is obvious that it is through the sanatoria deaths that the southern group rate has been made so high. Of course, there are other sanatoria in the state but the southern sanatoria have the widest sphere of influence. The State Sanatorium at Howell in Livingston County receives patients from the entire state. Of the 25 deaths which occurred in this sanatorium in 1926, 8 were residents of the central counties, 6 of the northern counties, 6 of the southern counties, 4 of Wayne County and 1 of the Upper Peninsula. Not one of these patients was a resident of Livingston County in which the sanatorium is located.

It will be recalled that deaths are required by law to be registered in the district in which they occur and while it is very easy to pick out the non-resident deaths, it is by no means easy to reallocate these deaths to the district of residence.

Yet considering these as county deaths, the Livingston County 1926 rate would be 76.5, but omitting these deaths the Livingston County rate would fall to 38.6, which is not at all out of harmony with the northern and southern county group rates.

Again take Calhoun County: here the rate was 106.0 in 1926. Three hospitals are located here which should be considered. The

County Hospital, while not in the city of Battle Creek, showed that 9 out of the 10 deaths were residents of Battle Creek and none were from outside of the county. The U. S. Veterans' Hospital showed 3 tuberculosis deaths, 1 from Wayne County and 2 from the Upper Peninsula. The American Legion Hospital at Camp Custer with 250 beds is the most important. It is primarily for tuberculosis patients and 53 deaths occurred there in 1926, only 2 of which were residents of Calhoun County. Twenty-seven came from Wayne County, the others being scattered and 3 being from outside of Michigan.

The Wayne County deaths should be charged to Wayne County which will, of course, increase that rate. The point is that the corrected Calhoun rate is 40.2, which is a great deal less than the record of 106.0 and is comparable to the more favorable northern and central group rates.

A correction for Washtenaw County would also show a decrease in the county rate of 129.6. The University of Michigan Hospital is located here and, while this is by no means a tuberculosis institution, there were many deaths

from tuberculosis, and as the University Hospital furnishes a service to the entire state these deaths were widely scattered.

On the other hand let us consider two counties in which no downward revision of the rate need be made. It is true that if the deaths in the large institutions previously considered were properly charged to these counties, the rate would rise but the increase would be but slight. These counties are Jackson and Ingham, each with a large city (Jackson and Lansing) where we would expect the rate to be somewhat higher, due to the urban influence, but we only have an actual rate of 55.6 and 47.5, respectively.

To recapitulate then, the high death rate in the southern county group may be explained in two ways: First, the city of Detroit, with an uncorrected rate for Wayne County of 93.5 which corrected would be even higher. The urban influence is quite evident. Second, the presence of the sanatoria in the southern counties which minister to the needs of the whole state.
